INDEX TO VOLUME I FOR 1918.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society; Paris, France; Berlin, Prussia, Germany; Vienna, Austria, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

ABBOTT, Captain William F., Military Cross conferred upon, 130
 ABBOTT, Captain William Norman, Military Cross conferred upon, 465
 Abdomen, gunshot wound of, in a boy (Edward J. Donville), 371
 Abdomen, gunshot wounds of, at a casualty clearing station (Captain R. Charles), 337. (O)—A correction, 388
 Abdomen, penetrating gunshot wound of, in civilian practice (A. R. Walters), 175
 Abdomen, treatment of wounds of, 28
 Abdominal cases, selection of, for operation (Colonel Owen Richards), 471. (O)
 Abdominal operations at an advanced operating centre (Captain Charles F. M. Saint), 473. (O)
 ABERROMBIE, Captain Rodolph G.: Prognosis in war nephritis, 504. (O)
 Abortion "contagious" in cows, 193
 Abortion, tubal, with cystic degeneration of the ovary on the same side (Robert B. Johnston), 590
 ABRAHAM, Captain Everard Cecil, Military Cross conferred upon, 517
 ABRAHAM, Major James J., D.S.O. conferred upon, 467
 Abscess of liver, amoebic (Captain R. J. McNeill Love), 696. (O)
 Abscess of testis due to *Bacillus coli* (W. Gifford Nash), 149. (O)
 ACADEMY, ROYAL, OF MEDICINE IN IRELAND: *Section of Medicine*—Wallace Beatty: Rodent ulcer, 206—Major W. G. Harvey: Value of x-ray treatment, 372—Discussion on the treatment of syphilis, 482
Section of Obstetrics—Hastings Tweedy: Treatment of tubal sterility, 373
Section of State Medicine—Dr. Kirkpatrick: Control of syphilis, 602
 Acid, plant nucleic, method for manufacture of (A. Chaston Chapman), 685
 Acidosis and death (leading article), 540
 Acidosis as a possible cause of certain symptoms in diphtheria (B. A. Peters), 10. (O)
 Acidosis, review of books on, 17
 ADAM, Captain George Min, Military Cross conferred upon, 130
 ADAM, James: Notes on asthma, 113. (O)
 ADAM, Lieut. Col.: Appreciation of John McCrae, 190—*Medical Contributions to the Theory of Evolution*, rev., 619—Adaptation and disease, 659, 737
 ADAMS, Lieut. George Gordon Crymble, dies on service, 382
 ADAMS, Captain Jos. E.: Simple method of mechanical fixation for fracture of long bones, 12. (O)
 ADAMSON, H. G.: Sycoosis and other chronic staphylococcal infections of the skin and their prevention, 8. (O)
 Adaptation and disease, 632, 658, 683, 737
 Adenoids and tonsils, survey of 1,064 operations for complete removal of (Edward D. D.

Davis), 114. (O)—Correspondence on, 216, 248
 Adenoma of umbilicus (C. Hamilton Whiteford), 564
 ADDIS, Captain William Robert, Military Cross conferred upon, 517
 ADEY, Lieut. Col. John Kellerman, O.B.E. conferred upon, 680
 Adrenalin in dyspepsia with gastric atony, 738
 Aeroplane accidents, loss of head in (Captain J. Eaton Lascelles), 535
 Aeroplanes accidents, medical aspects of (Surgeon H. Graeme Anderson), 73. (O)
 Africa, East, the campaign in, 464
 Africa, West, information for candidates for the medical staff, 415
 AGASSIZ, Captain Cuthbert Delaval Shafto, Military Cross conferred upon, 97—Bar to Military Cross, 187
 Agglutination in diagnosis of dysentery. *See* Dysentery
 Aides-de-camp for medical general officers, 604
 AIRMAN, Staff Surgeon-Colonel, obituary notice of, 274
 AINSLEY, Captain A. C., Military Cross conferred upon, 411
 Air Force Medical Service, the Royal (leading article), 23, 123, 486—Note on, 89—Parliamentary questions, 186, 212, 267, 295, 323, 354, 599—R.A.M.C. and, 295—Suspended officers R.N. and R.A.M.C., 415—Medical Committee, 599. *See also* Aviation and Flying
 Air, hot, simple appliances for field units (Lieut. Col. C. Max Page), 480. (O)
 Air-raid shelters and spread of infectious diseases, 274
 Air raids, shell-shock patients in, 90
 Air service, selection of candidates for (Surgeon H. Graeme Anderson), 314—Discussion, 316
 Aisne, French wounded from, 215
 AITKEN, Charles J. Hill: Nasal obstruction as a cause of hunger, 118
 AITKEN, Captain D. McCrae, correction of bony deformities, 671
 AITKEN, Surgeon Robert: Case of pyaemia treated with intravenous injections of eosul, 369. (O)
 Alarminist, psychology of the, 651
 ALBERT, J.: Infantile beri-beri, 218
 Alcohol: its Action on the Human Organism, report of committee, 238
 Alcohol and food economy (A. R. Cushny), 211
 Alcoholism in women, effect of liquor control on, 19
 ALDERSHOFF: Typhoid vaccine, 522
 ALDERSMITH, H., obituary notice of, 496
 ALDERTON, Captain Wilfred H., Military Cross conferred upon, 655
 ALDRIDGE, Lieut. Col. Arthur Russell, C.B. conferred upon, 30
 ALEXANDER, Lieut. Col. J. D., Belgian Croix de Guerre conferred upon, 327
 ALEXANDER, Captain Robert H., Military Cross conferred upon, 655
 ALI IBRAHIM BEY, M.B.E. conferred upon, 681
 ALLAN, James, O.B.E. conferred upon, 680

ALLARDYCE, Lieut. George Gilmour, dies on service, 630
 ALLBUTT, Sir Clifford: Thrombosis and embolism, 385—Case of Huntington's chorea, 389 (O), 413
 ALLEN, Captain Francis J., Military Cross conferred upon, 655
 ALLEN, Captain William Barnsley, bar to Military Cross, 97
 ALLISON, Captain Herbert C., Military Cross conferred upon, 66
 ALSTON, Captain John, Military Cross conferred upon, 325
 ALTHORP, Charles Frederick M., obituary notice of, 495
 ALTOUNYAN, Lieut. Ernest H. R., Military Cross conferred upon, 66
 Ambulance de "L'Océan" La Panne, 402
 Ambulance work, principles and practice of (Sir James Cantlie), 260
 America. *See* United States
 America in the war, committee appointed to collect materials for American medical history of the war, 187
 American Journal of Ophthalmology amalgamates with various other journals, 579
 American Revolution, military hospital service in, 416
 American specialists, mission of, 211
 American women's hospital sends twelve women to work in France, 64
 American wounded in England, hospital treatment of (parliamentary question), 653
 AMESBURY, Major Frederick Cholmondeley Dering, dies on service, 270
 Amosbic dysentery. *See* Dysentery
 Amoss, H. L.: Acute poliomyelitis in a carrier, 157—Acute poliomyelitis and streptococci, 405
 Amputation flap retractor, 347
 Amputation, guillotine, 185—(Major R. W. Murray), 230
 Amputation stumps, pains of (Major Edred M. Corner), 665. (O)
 Amputations, ciematia (V. Putti), 635. (O)—Note on, 651
 Amyl nitrite inhalations in diagnosis of mitral stenosis (Lieut. R. A. Morison), 452. (O)—Correspondence on, 577
 AMYOT, Major John Andrew, C.M.G. conferred upon, 31
 Anæmia, pernicious (R. Thorne Thorne), 645
 —Correspondence on, 686
 Anaerobic bacteria. *See* Bacteria
 Anaesthesia, chloroform, physiology of (G. A. Buckmaster), 619
 Anaesthesia, nitrous-oxide-oxygen, simple apparatus for (Captain A. S. Wilson), 78. (O)
 Anaesthetics in military hospitals (Lieut. Thomas Clarke), 79. (O)
 Anaesthetists in military hospitals, pay of, 137
 Anal fissure, quinine in treatment of (Helen G. Leyton), 314
 Analgesia, general, by oral administration (Captain James T. Gwathey and Captain Howard T. Karsner), 254. (O)—Correspondence on, 301, 413

- Anatomical nomenclature, 378
 Anatomy, teaching of (leading article), 432
 ANDERS, James M.: *Textbook of the Practice of Medicine*, rev., 430
 ANDERSON, Captain Archibald S. K., D.S.O. conferred upon, 130, 546
 ANDERSON, Elizabeth Garrett, memorial to, 212—Estate of, 443
 ANDERSON, Surgeon H. Graeme: Medical aspects of aeroplane accidents, 73. (O)—Selection of candidates for the air service, 314
 ANDERSON, Lieut.-Col. Henry Stewart, C.M.G. conferred upon, 31
 ANDERSON, Captain John, D.S.O. conferred upon, 31
 ANDERSON, Captain John G., Military Cross conferred upon, 66
 ANDERSON, Lieut.-Col. John H., C.B.E. conferred upon, 67
 ANDERSON, Captain Jonas William, killed in action, 438
 ANDERSON, Captain Robert P., Military Cross conferred upon, 655
 ANDERSON, Sir W. M. Abbot: University representation in Parliament, 520
 ANDERTON, Lieut. James E. H., Military Cross conferred upon, 66
 ANDERTON, Captain William D., Military Cross conferred upon, 655
 ANDREWEES, F. W.: Histological notes on two fatal cases of icterus gravis following injections of novarsennobilin, 443
 ANDREWS, Lieut. Henry John, M.B.E. conferred upon, 681
 Aneurysm of the third part of the left subclavian artery (Herbert H. Brown), 617. (O)
 ANGELL, Lieut. H. J., Serbian Order of St. Sava conferred upon, 159
 Angina, Vincent's (Captain A. J. Eagleton, Captain J. D. Mercer, and Captain F. E. Hudson), 15
 Angina, Vincent's, serological investigation of (Frank E. Taylor and Captain W. H. McKinstry), 82. (O)—Correspondence on, 160, 583
 Angina, Vincent's, treatment of, 220
 Angina, Vincent's, ulcerative gingivitis (J. F. Colyer), 205
 Animal extracts, early therapeutic use of, 607
 Ankylostomiasis campaign in Costa Rica, 193
 ANTILL-POCKLEY, Lieut. John G., killed in action, 491
 Antimeningococcal serum in cerebro-spinal fever, 598
 Antiseptics, action of on bacterial toxins, 626
 Antiseptics in treatment of empyema (R. Atkinson Stoney), 198. (O)
 Antibiotic serum for gas gangrene, 62
 Antityphoid lipovaccine, 240
 Antivaccinists, object lesson for, 498
 Antiveneroleague formed in Cuba, 674
 Antiviscerionists and the Red Cross, 705

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, JANUARY 5th, 1918.

SOME SURGICAL DEVELOPMENTS IN WOUND TREATMENT DURING THE WAR.

BY

COLONEL A. W. MAYO-ROBSON, A.M.S., C.B., C.V.O.,
F.R.C.S.,

CONSULTING SURGEON TO THE SOUTHERN COMMAND.

It might have been thought that the experience gained in civil practice would be directly applicable to war wounds, but this holds good only to a limited extent. Virtually all war wounds, with the exception of some bullet wounds, are not only septic but virulently septic; this is due to the contamination of the skin and clothing, as well as the fragments of shell and other foreign bodies driven into the tissues, by the germ saturated soil of the highly cultivated lands of France and Belgium.

At the present time the following distinct methods of wound treatment are being employed, and some of these have several or even numerous modifications:

1. Asepsis.
2. The treatment of septic wounds on general principles: free incision, removal of foreign bodies, thorough irrigation with or without antiseptics, and free drainage.
3. Antiseptics as introduced by Lister, and its modifications.
 - (a) The use of alcohol alone, no water or watery solution coming near the wound.
 - (b) The use of various more or less poisonous antiseptics, such as carbolic acid, mercury perchloride, mercury biniodide, iodine, potassium permanganate, eusol, flavine, chloramine-T, brilliant green, etc.
 - (c) The Carrel-Dakin treatment, the continuous use of a solution of sodium hypochlorite.
 - (d) Antiseptic pastes, such as treatment by bipp, introduced by Professor Rutherford Morison, or its modification by the use of other pastes
4. Physiological treatment, introduced by Sir Almroth Wright, who uses a hypertonic salt solution. Arising out of the latter, but distinct from it, the salt pack, introduced by Colonel Gray.
5. Surgical treatment—complete excision of the wound, including all contaminated parts and foreign bodies.
6. Bacteriological treatment, introduced by Dr. Donaldson and Major J. Leonard Joyce—that is, the introduction of a beneficent organism to kill the malignant germs.

A true perspective of the subject can probably best be obtained by one, possessing the necessary technical knowledge, who can remember the pre-antiseptic days and who has watched and taken part in the various developments of the scientific treatment of wounds. With an open mind he can appreciate the advantages and disadvantages of the various theories and methods and their practical application.

In the pre-antiseptic days surgery had little better to offer than the safe piloting of a patient through the inflammation which was almost certain to ensue on any wound, or to remove an injured limb in anticipation of the severe constitutional symptoms certain to follow an opened joint or a severe compound fracture.

I have always felt profoundly thankful that it fell to my lot to commence surgical work during the pre-antiseptic days, and as a post graduate to become a pupil and humble follower of that great genius who transformed surgery from an art to a science.

In the consideration of the germ theory of putrefaction

as applied to infected wounds and their treatment, there are, however, other possibilities to be considered beyond the attempt to kill the micro-organisms by poisonous substances that also do harm to the living cells of the host.

We all have, fortunately, the faculty in a greater or less degree of being able to destroy bacteria when they have entered the body, but some individuals have it in greater degree than others; they are less prone to catch infectious ailments, and their wounds heal kindly under simple treatment. It follows from Metchnikoff's observations on phagocytosis that if the cells are in a vigorous state, as they are in a person in good health, he will be able to offer battle to our tiny but formidable adversaries with every probability of success; but the opposite holds also, and if the system is lowered by intemperate living, by excess of any kind, by overwork, want of exercise, insanitary surroundings, impure air, want of proper food, or in any other way, then the bacteria will find a suitable soil in which to grow, as the living cells are killed in the attempt. When the dead cells accumulate to a perceptible degree we speak of them as pus, which itself then becomes a source of trouble, and must be got rid of before recovery can occur. If only a few germs gain access to a wound, as in an ordinary clean bullet wound, or as even may be the case in a clean surgical operation, Nature should be quite capable of dealing with them; whereas, if large numbers are admitted, as, for instance, in the case of a portion of shell being driven through the dirty clothing and then through unpurified skin before it comes to lodge inside a limb, unaided Nature is powerless, and unless the surgeon intervenes, loss of limb or life is extremely probable.

TREATMENT ON GENERAL PRINCIPLES.

The foregoing explanations render it easy to realize why aseptic surgery has in a great measure replaced antiseptic surgery in the civil practice of the modern surgeon, and why antiseptic surgery in some form or other is necessary for the treatment of war wounds.

Aseptic surgery—that is, surgery carried out under the strictest and most rigid conditions of cleanliness—avoids the use of poisonous antiseptics such as carbolic acid and the mercury preparations, which it has been clearly proved damage the tissues and kill the living cells, which will themselves destroy any germs that might be accidentally introduced. For many years before the war I had carried out the principles of rigid aseptic surgery, and the satisfactory results obtained absolutely convinced me that the use of strong poisonous antiseptics was not only unnecessary but injurious in ordinary work.

When the war opened, my experience first in one of the London war hospitals, later at the front in France, and afterwards in Egypt and at the Dardanelles, confirmed my previous impressions that carbolic acid and other poisonous antiseptics were to be avoided, even in the treatment of septic war wounds.

When at the Dardanelles the wounded were brought off to the hospital ships within a few hours of being wounded, and I there had the opportunity of operating on a number of abdominal cases—among others such as gastric, intestinal, liver, and other visceral wounds—in all such cases aseptic treatment was employed and with great success, the use of strong antiseptics in the peritoneal cavity being, I consider, absolutely contraindicated.

We, however, soon realized that with the exception of a few through-and-through wounds, all other gunshot injuries, especially shell wounds, were virulently septic, and required rigorous treatment by free incision and removal of bits of clothing and other foreign bodies, and

by thorough irrigation with salt water or plain boiled water, or some mild antiseptic such as a weak permanganate solution, repeated as often as practicable, and free drainage. This led to the prevention of gas gangrene (at first a terrible scourge) and to good surgical results; it was the means of saving many lives or limbs that otherwise must have been lost.

The more efficient methods of treatment which enable wounds to be purified and closed at an early stage had not then been introduced. Nevertheless, by the means I have related, and which we may speak of as treatment on general principles, we were able to attain very fair results, and to put a stop to the practice of amputating in nearly all cases of gas gangrene.

When with the Mediterranean Expeditionary Force, I had the advantage of spending some little time on two hospital ships with Dr. Dakin, and of trying his solution on wounds before it had been generally adopted. I was then convinced that the hypochlorite solution, since known by his name, was the most efficient antiseptic hitherto employed, for while it was an active bactericide it apparently did not seriously damage the tissue cells. The great difficulty was that in dealing with very large numbers of wounded, with limited staffs of surgeons and nurses and with inadequate accommodation, it was physically impossible to irrigate the wounds as frequently as we knew to be desirable. The hospital ships, of course, afforded only temporary accommodation for the wounded, which were transported as speedily as possible to the base hospitals in Egypt, Malta, and elsewhere, where more elaborate treatment could be carried out.

ANTISEPSIS.

Antiseptic surgery, introduced by Lister, but since modified and improved in many ways, aims at killing the germs already introduced into wounds, but the perfect antiseptic, which, while fatal to germ life, is not injurious to the living cells in the wound, has yet to be discovered.

The strong poisonous antiseptics, such as carbolic acid, mercury perchloride and biniodide, are now only used externally, to purify the skin, and they have in the hands of modern surgeons been replaced as a rule by milder non-toxic drugs, which are better bactericides and less injurious to the living cells in the wounds, from which help is sought in the healing processes.

My first experience of an antiseptic operation, long before Lister introduced his system, was in 1875, in Glasgow, and the case was one of amputation of the thigh for senile gangrene. After steeping the hands and instruments in spirit, the limb as well as the wound were washed in pure whisky and dressed with lint soaked in the same spirit. No drainage was employed. The wound healed by first intention, and the patient, a man of over 70, made a good recovery.

Where other means are not available, alcohol used in this way is most efficient, and as it is generally available in nearly every household, a surgeon need never be powerless for want of an antiseptic in the most out-of-the-way place. I have frequently used it successfully.

Two recently introduced antiseptics—flavine and brilliant green—we owe to work at the Middlesex Research Laboratory. Flavine used in a strength of 1 in 1,000 has been extensively advertised both in the lay and in the medical press, but it has not realized in practice all that has been claimed for it. It may be used to irrigate recent wounds or as a pack in large infected wounds, or it may be employed by means of Carrel's tubes instead of Dakin's fluid. Some surgeons speak well of it. It is non-poisonous and non-irritating, but it stains everything a brilliant yellow. Although, as a rule, it tends to clean dirty wounds, in some cases it appears to retard healing by destroying the new epithelium at the wound margin and retarding the growth of granulation tissue, thus necessitating a change of dressing in the later stages of the case. The pathologists of various hospitals have reported that it is not an efficient bactericide, and in no cases is it safe to attempt the closure of wounds by suture after treatment by flavine, as is done in the Carrel-Dakin treatment.

Brilliant green is used in the same way as flavine, and has been especially useful in staining wounds as a preliminary to excision. It is spoken well of by many surgeons who have employed it in the treatment of war wounds. I saw it used extensively when with the Mediterranean Expeditionary Force.

Eusol is one of the most efficient antiseptics the surgeon can employ, and is closely allied to Dakin's fluid; it is easily prepared, keeps well in ordinary bottles, and is non-poisonous. This chlorine preparation, unlike Dakin's fluid, is stable, and therefore available in situations where there is no chemist at hand to give a regular daily supply of freshly made lotion.

Chloramine-T is also an extremely useful antiseptic, coming under the same class as eusol and Dakin's fluid.

The ordinary antiseptic methods leave very much to be desired; as although, by free incision, removal of foreign bodies, thorough irrigation with some antiseptic and free drainage, virulent sepsis and gas gangrene can as a rule be effectually treated, the patient is left in many cases with enormous granulating wounds that take many weeks or even months to heal, leaving him a wreck constitutionally, and with enormous disfiguring and disabling scars, leading to deformity and rendering him unfit for military or other work.

Carrel-Dakin Treatment.

This modification of antiseptic treatment has been a real surgical advance, for in the course of a few days (from 5 to 14), if properly carried out, it usually renders septic wounds sterile, and enables them to be completely closed by sutures, thus doing away with the long-continued discharges of an ordinary granulating wound, and saving the patient from a wearisome and painful illness, ending in deterioration of health and deformities due to huge scars.

After meeting Dr. Dakin at the Dardanelles, and using his fluid successfully in numerous gunshot wounds, I met Dr. Carrel in France, and had the opportunity of seeing the Carrel-Dakin treatment carried out in recent wounds as well as in cases already very septic. When carried out as the authors suggest it is most successful; but I am bound to confess that in many hospitals where I have seen what professed to be the Carrel-Dakin treatment, it was anything but successful, as the fluid was not carefully or freshly prepared, the surgeons did not carry out the after-dressings personally, and the aid of a pathologist was not obtained.

In the French hospitals the solution is carefully tested by skilled chemists, the operative technique and the after-dressings are carried out by the surgeon himself with as much care as in any aseptic operation, and the discharges are regularly examined by a skilled pathologist. So soon as the wound fluids are sterile or are found to contain only one or two germs in several microscopic fields, the wound can be completely closed from end to end by sutures and it heals like a primary operation wound.

The multiple irrigation tubes, perforated along their whole length, 4 mm. calibre and 30 cm. long, are inserted into the depths and recesses of wounds, and enable the nurse to flush the wound with a little of the solution every two hours by means of a clip on a tube leading from a glass reservoir suspended over the patient. In this way the wound is kept constantly bathed with the Dakin solution and the pathogenic germs are destroyed and prevented from developing.

The appearance of the patients thus treated is very striking, they have a clear complexion, are free from pain, have no rise of temperature, have a good appetite, and, with few exceptions, even the most extensive and foul wounds become sweet and clean and can be completely closed by suture within a fortnight or even earlier in some cases. A great disadvantage is the difficulty of carrying out this treatment during transport, which has given a very wrong impression to surgeons working in England, as the cases often arrive in a very foul condition and compare unfavourably with those treated by salt packs or by "bipp."

Antiseptic Pastes.

The antiseptic paste called "bipp" from the initials of its components—bismuth, iodoform, and paraffin—was introduced by Professor Rutherford Morison, and as a primary or secondary dressing in gunshot injuries has proved to be most effective. Cases treated with it can be transported safely without fear of becoming septic from want of dressing during the journey, and in this respect it has advantage over the Carrel-Dakin treatment.

Mr. Rutherford Morison's statement with regard to the treatment in his hands may be read in his article published in the BRITISH MEDICAL JOURNAL for October 20th, 1917. Bipp, I find, can be used in cases treated by the Carrel-Dakin method for a few days, and when the wound is not

yet absolutely sterile the use of the paste enables it to be safely closed by suture, thus saving time and trouble to the patient and attendants. Captain Hey prefers a paste without bismuth or iodoform but containing brilliant green, boric acid, french chalk, and liquid paraffin, which he uses with great confidence after excision of the infected part as a primary measure, or after the Carrel-Dakin treatment as a secondary procedure. His results closely resemble those obtained by the use of bipp.

PHYSIOLOGICAL METHOD.

Sir Almroth Wright is an opponent of antiseptic surgery, and suggested the use of hypertonic saline solution—the so-called “physiological treatment,” which, he claims, draws out from the tissues of the wounds an abundant fluid containing cells, which attack and destroy the germs of disease; and that these, together with bits of dead tissues and dead cells, are carried away by the free outpouring of fluid. A dressing wet with the hypertonic saline solution must be left in the wound or the wound must be kept constantly irrigated with the fluid. The chief merit of this treatment lies in the fact that it helped to break the spell which had bound surgeons to antiseptics in the treatment of wounds essentially septic.

Out of this method Colonel H. M. W. Gray evolved the “salt-pack” treatment to promote a so-called lymphagogue action, thus obviating the need for drainage or continuous irrigation. The great merits of the salt pack lie in the ease with which it can be applied, and in the fact that it can be left *in situ* for several days without renewal, thus saving the patient the distress and pain of frequent dressings; that it accomplishes all the changes which Sir Almroth Wright insists upon as being necessary for the successful cleansing of a wound from infection, and that its effects are not interfered with by the transport of the patient.

Although the bacterial flora of the wounds treated by the salt pack are numerous and the discharges are offensive, the wounds do well as a rule, become clean, are speedily covered by healthy granulations, and heal rapidly; moreover, wounds treated by salt packs are extraordinarily free from secondary hæmorrhage.

The process is simple in the extreme. After opening up and purifying the wound as far as possible, the salt packs are placed in it, and over all an absorbent dressing; as the dressing does not need renewing for some days, the saving of time to the attendants is very considerable.

Hitherto the good results have been attributed in some obscure way to the salt acting more or less on the physiological lines suggested by Wright, but all who have witnessed the employment of salt packs have felt that some other explanation is necessary. This I shall have to refer to later in considering the pathological treatment of wounds.

THE SURGICAL METHOD.

In gunshot injuries, besides the introduction of pathogenic organisms, there is in every case actual destruction of tissue by the force of entry of the projectile; there is necessarily, therefore, a varying amount of dead or devitalized tissue present. It is in this that the organisms elaborate the poisons, and it is from this source that the toxins enter the system. If the dead tissues can be removed the source of the poison is taken away. The strong antiseptics, which aim at killing the germs in the wound, only effect their purpose partially and slowly; not only do they fail to remove the dead tissue which is the breeding ground, but they produce more by their destructive effect on the living cells. Even under the continuous application of the Carrel-Dakin method, from five to fourteen or more days are required before the wound is rendered sterile.

The physiological method, which relies on the living cells throwing off the dead tissues and destroying the pathogenic organisms, is long and uncertain in its action; moreover, while dead tissues remain, they are a source of danger and capable of again lighting up fresh mischief. Hence, the tendency of surgery now is at as early a stage as possible to excise the whole of the infected area—or, in other words, the dead and damaged tissues. But in doing this it inflicts a fresh injury, often very extensive, and one liable to re-infection.

Captain Wilson H. Hey says that the case for complete excision should begin and end all discussions on the wounds of war; without it good antiseptics and pastes are

almost useless. He stains the whole of the wound with brilliant green, and, if possible, excises the wound without allowing the knife to enter the wound cavity; the wound is pasted and primarily sutured in some cases, but in others, especially where a complete primary operation cannot be done, every trace of stained tissue is excised, the wound is dried throughout with spirit, and the paste rubbed into the tissues, and with all thoroughness into every recess. When all is going well the dressings are not disturbed for two or three days, and if the suture counts average only 0.2 to 2.0 per field the wound may be sutured on the third to the fifth day. Where progress is unfavourable the wound is repasted, or further operative measures may be required under anaesthesia; in some cases hot fomentations are used, and suturing is only performed at a later stage.

It will be seen that this method, which is only available if the case is seen early, and involves a more or less severe operation, not only saves much time in the healing of the wound, but also saves the patient from the dangers of sepsis and secures a more or less linear scar. This treatment should only be carried out by a skilled surgeon, otherwise material deformity may be inflicted if the wound be extensive.

BACTERIOLOGICAL TREATMENT.

The bacteriological treatment of wounds is the result of very interesting work carried out at the Reading War Hospital by Dr. Robert Donaldson and Major J. Leonard Joyce, F.R.C.S., in septic wounds of all kinds arriving from the front at various periods after the injury has been inflicted.

Major Joyce, who is a strong advocate of the salt-pack treatment, noticed that under this treatment the wounds that were doing well emitted a powerful and offensive odour, and those not doing well were devoid of smell.

The observers found in the offensive discharges of the cases that did well an oval sporing bacillus which was absent from the cases not doing well, and they ultimately isolated it in pure culture. This organism, when introduced into a fresh meat-broth tube and incubated at 37° C. anaerobically, in two or three days emitted the characteristic wound odour and the meat began to blacken and diminish in volume, indicating active proteolysis. This at once suggested the part possibly played by the bacillus in wounds—namely, that it did in the dead wound tissues what it appeared to do in the glass tube—that is, it digested them.

As the organism was found to be non pathogenic to animals and as the fluid in which it was grown contained no elements toxic to animals, it was considered safe, after thorough irrigation and purification, to introduce it into wounds that were not doing well under salt packs; with the result that the characteristic odour soon developed, the temperature came down, the patients became comfortable, and in a few days the wounds became clean, devoid of sloughs and covered with healthy granulations.

The question then arose as to the part played by the salt, and it was found that the wounds containing the anaerobic germs (now called the Reading bacillus) did as well when sphagnum moss replaced the salt; in fact the idea that the salt has any specific value is exploded.

Thus a point has been reached in which can be recommended a treatment which involves the simplest technique, the simplest and cheapest of dressings (for salt or sphagnum moss can easily be obtained) and the least disturbance to the patient. It does away with the need for frequent dressings and the mental and physical sufferings entailed thereby.

In order to ensure success, however, it is necessary that the organism or its spores be present, and although it frequently is, it cannot be depended on to be present. Hence in such cases the wound ought to be sown with the organism at the time of packing. In fact, it reminds one of the old adage, “Set a thief to catch a thief.”

In treating wounds by this method it is important to lay them freely open, every pocket being dealt with, all foreign bodies removed, and any grossly damaged tissue taken away. The wound must then be irrigated with sterile water or saline solution, and the pure culture of the Reading bacillus introduced by means of a pipette. The packing of salt or sphagnum moss moistened with sterile water is then introduced into the wound so as to bring it into contact with every part, over this several layers of

plain moist gauze are laid, and over all a thick layer of cotton-wool, after which the whole is bandaged firmly. A splint is an additional advantage.

If all is going well, as shown by the general condition, the pack is left in for about seven days (about the third day the characteristic odour will develop), when it can be removed and the granulating wound irrigated with warm normal saline or eusol solution, after which a healthy wound only requires treatment, and either by the Carrel-Dakin method or by the use of antiseptic paste it can soon be closed by suture.

SELECTION OF METHOD.

With all these methods of wound treatment to choose from I may be asked which I prefer.

In cases seen at the front the first duty of the surgeon in all shell wounds is to lay the wound fully open, including every pocket, to remove all foreign bodies and bits of clothing as well as loose particles of bone and dead or damaged tissue, to arrest bleeding, and to irrigate the wound thoroughly with some antiseptic such as eusol or Dakin's fluid, or hypertonic saline or alcohol—in fact, to treat the case on the general principles well known as suitable for poisoned wounds; this, followed by free drainage, was the method carried out with more or less success in the early months or first year of the war.

Now, although this led to saving of life and to abolishing violent sepsis and gas gangrene, it left large wounds to heal by a long process of granulation, and led to exhaustion of vital powers and to deformity caused by large scars. Now, however, we have several methods to choose from to shorten the treatment subsequent to the first necessary operation.

(a) The Carrel Dakin treatment, with closure of the wound in from a week to a fortnight, is, if the case can be got shortly to a good hospital and kept there, the ideal method, and it has certainly given excellent results, but it is not good for cases that have to be transferred by sea and rail.

(b) If the patient has to be transferred—as, indeed, have the greater number of cases—after cleansing the wound and drying it with alcohol, the bipp treatment with closure of the wound affords an excellent method; this is especially the case if the wound has been completely excised, when either bipp or the paste recommended by Captain Hey can be used.

(c) The salt-pack treatment used by Colonel Gray is excellent both for transport and subsequent treatment, to be followed in about a week or more by the Carrel-Dakin or bipp methods.

(d) For the care of septic suppurating wounds arriving constantly at the base hospitals both in France and in England, the pathological method followed out at Reading of grafting the purified wound with the Reading bacillus under packs of sphagnum moss is both simple and effective, and the experience there is that secondary haemorrhage has never occurred under this treatment.

The modern treatment of gunshot wounds gives ample scope for the skill of both surgeon and nurse, and is attaining a state of perfection that could hardly have been expected by those who saw the dreadful prevalence of gas gangrene and its treatment by amputation in the early stages of the war.

Whatever the other services engaged in the war may or may not have done, I think we can without hesitation say that the medical services and the nursing service have both "made good," to use a term coined on the other side of the Atlantic.

When the war started we had a small Army Medical Service to meet the needs of our "contemptible little army," to use the Hun expression. The administrative work that this small service has accomplished under the genius of our present Director-General, Sir Alfred Keogh, has been phenomenal, and can only be appreciated by those who know the difficulties that have had to be met; but I venture to think that it will figure largely in the history of the war.

The way in which the civil branch of the profession has taken up its work as part of the medical service of the army is not the least wonderful record of a great sacrifice. The leading physicians and surgeons giving up their consulting practices have, the former, thrown themselves into the prevention of disease as well as its treatment, and the

latter have undertaken the treatment of the legitimate risks of war—wounds and casualties. From their ranks have also been drawn the army consulting physicians and surgeons to act and advise wherever the British army is on active service.

Not only this, but all the towns and villages of the empire, whether in the colonies or at home, have spared so many of their doctors and surgeons that the civil population has had to make no little sacrifice in order that the numerous war hospitals and hospital ships almost all over the civilized world might be staffed with physicians, surgeons, anaesthetists, and specialists of all kinds, who have performed their many duties with the same skill and care that they previously gave to their private patients.

The work of the nursing service is beyond all praise; they have been the ministering angels ever ready and always present to give help and comfort to the sick and wounded. Wherever they move they carry with them the gleam of the ideal—the symbols of love, mercy, patience, and sacrifice. I have seen many of them in the thick of the work, when the wounded were coming straight from the battlefield and where the sad sights were enough to blanch the stoutest hearts, never flinching, but steadily pursuing their beneficent duties. Not a few of them have given their lives to the cause—some have been killed by the shells of the enemy, others have died from disease contracted when on duty, others have been drowned when serving on hospital ships, and one at least has suffered martyrdom, but still their numbers increase and still more are wanted.

THE TREATMENT OF GONOCOCCAL ARTHRITIS BY SENSITIZED GONOCOCCAL VACCINE.

BY

CAPTAIN H. D. HAWORTH, R.A.M.C.(T.C.),
BACTERIOLOGIST, NO. — GENERAL HOSPITAL.

SENSITIZED VACCINES were first employed by Besredka in 1902. He prepared vaccines of this type for prophylactic use against cholera, plague, and typhoid fever, sterilizing by heat either before or after sensitizing with the specific serum. He claimed that active immunity was produced almost immediately and with little local reaction or constitutional disturbance.

Later, Broughton-Alcock employed sensitized living vaccines in the treatment of infections of the staphylococcal, gonococcal, and streptococcal types. He obtained his specific serums for the purpose of sensitizing the cultures by first administering to the patient an ordinary vaccine of the infecting micro-organism, and using the serum of the patient thus infected to sensitize the living vaccine.

In 1913 Lieut.-Colonel Gordon, R.A.M.C., published a paper in the *Lancet* on "Sensitized vaccine in acute bacterial infection," in which he gave the results obtained in a series of cases. He showed that in the treatment of all types of infection by *Streptococcus pyogenes* (among these he includes streptococcal septicaemia and post-puerperal streptococcal endometritis), out of nineteen cases treated twelve showed great improvement after administration of the vaccine. He admits disappointment at the results obtained after employing sensitized staphylococcal vaccines. However, the results in the streptococcal infections above mentioned suggested that it might be useful to try the administration of sensitized gonococcal vaccine in the joint infections which, as a rule, improve very slowly or not at all with the ordinary method of treatment.

The sensitized gonococcal vaccine was prepared in the following manner:

The first case treated was a patient whose knee-joint was affected. The swollen joint was aspirated and fluid removed which was markedly purulent.

A pure growth of gonococcus was obtained from this blood agar. This was subcultivated on blood agar at intervals of two days until a good growth resulted. Then a series of blood agar slopes were inoculated and incubated for twenty-four hours.

An emulsion of the growths on these slopes was made. 15 c.cm. of sterile saline solution (normal saline being used) was removed from each slope by means of a platinum loop, each loopful being washed off into the saline solution by agitation. The tube was then closed by a rubber cap and shaken vigorously by hand for ten minutes.

After this the amount of turbidity was noted and an approximate count made of the total number of gonococci (in millions) contained in the test tube. This was noted. Then 15 c.cm. of antigenococcus serum (B. W. and Co.) were added and the whole vigorously shaken to ensure thorough mixing of serum and bacterial emulsion.

The mixture was then incubated for twenty-four hours at 37° C. The tube was removed from the incubator after this and inserted in a test-tube rack (to retain it in a vertical position); this was then placed in a refrigerator for twenty-four hours. By this time the gonococci had formed a deposit at the bottom of the test tube.

The supernatant fluid was removed by hand pipette and 15 c.cm. of sterile saline solution added to the deposit. The whole was then well shaken, after which the tube was returned to the test-tube rack and replaced in the refrigerator for a further period of twenty-four hours.

After this the same procedure was followed, and the supernatant fluid was again removed and replaced with 15 c.cm. of sterile saline solution and the whole shaken and returned once more to the ice chest for twenty-four hours.

At the end of this time the supernatant fluid was again removed, leaving only the deposit, and 15 c.cm. of sterile saline solution were again added. To this was now added 1 c.cm. of a 10 per cent. solution of carbolic acid. The tube was well shaken and placed in the refrigerator for three or four days, during which period it was well shaken twice daily.

At the end of this time the bacterial emulsion was tested for sterility, and if sterile was ready for use. Having already noted the total number of gonococci present when the emulsion was first made, it only remained to divide this number by the figure 16 to obtain the strength of the vaccine in millions per cubic centimetre.

The first case treated was given this autogenous sensitized vaccine. The improvement in his condition encouraged me to continue the method, because he had previously been treated first with stock vaccine consisting of mixed gonococci and staphylococci, and subsequently with an autogenous gonococcal vaccine without apparent benefit, whereas when the sensitized vaccine was given a decided improvement in his condition was noted. However, the strain died, and as our numbers here are rather large to permit us to prepare an autogenous vaccine for each individual case, it was decided to employ a stock sensitized gonococcal vaccine prepared from several strains of the micro-organism.

Fresh strains of gonococci obtained from various urethral discharges were subcultivated several times, and then forty-eight hours cultures employed.

Four strains of gonococci were used in the preparation of the vaccine, and as a forty-eight hours' growth of gonococci does not emulsify so readily as a twenty-four hours' growth, the emulsion was made in the tube of sterile saline, the tube closed by a rubber cap, and then placed in a mechanical shaker, where it was kept vigorously shaken for one hour. At the end of this time the tube was taken out of the shaker, and the approximate strength of the emulsion in millions of gonococci noted.

The procedure then continued on the same lines as in the preparation of the autogenous sensitized vaccine just described—namely, addition of antigenococcus serum incubation for twenty-four hours, washing twice with saline, etc.

The advantage of using a sensitized vaccine in contradistinction to an ordinary vaccine is that one can push the dosage and still get practically no local or general reaction. Occasionally the patient will complain of the affected joint or joints being more tender to the touch within a period of several hours after the administration.

In dealing with the question of dosage a routine was tentatively drawn up as follows:

1st day	25 million of gonococci
2nd day	50 " "
3rd day	100 " "
5th day	150 " "
7th day	200 " "
9th day	250 " "
12th day	300 " "
15th day	350 " "
18th day	400 " "
22nd day	450 " "
26th day	500 " "
30th day	550 " "

Then an increase of 50 million every fifth day.

In the first series of cases this dosage was adopted.

CASE I.

This patient had a watery gleet on admission. There was marked swelling of the left knee, which was acutely painful. Temperature varied from 100° F. to 102° F. The joint was aspirated on three occasions and fluid removed.

He was given a stock mixed vaccine of gonococci and staphylococci without any improvement. This was followed by an autogenous gonococcal vaccine, during the administration of which the patient remained the same. A sensitized gonococcal

vaccine was prepared from this strain and administered according to the above-mentioned routine. He had the course up to the eighteenth day, when the dose was 400 million of gonococci. After the third dose the pain was easier, and the temperature came down to normal, at which, with an occasional rise, it remained practically all the time the patient was in this hospital. He could lie comfortably while at rest, but movement of the affected leg continued painful. He had been emaciated, but began to put on flesh rapidly.

After the administration of the vaccine on the eighteenth day he was transferred to England, where his temperature for six days was between 99° F. and 100° F., after which it remained normal. Pain on movement continued for three weeks, and swelling for four weeks, when the left knee showed half an inch greater circumference than the right.

CASE I.

Admitted February 24th, 1917, with purulent urethral discharge, and pain and marked swelling of the right knee. Vaccine treatment was commenced on the following day. The pain became easier and the swelling began to diminish on February 27th. The pain had disappeared on March 17th and the swelling on March 24th. The result was that the joints became quite freely movable and he was able to walk perfectly. The temperature on admission was 101.6° F. It fell to 100° on the fourth, was normal on the twentieth day, and so remained.

CASE III.

Admitted January 26th, 1917, with purulent urethral discharge and pain and swelling in finger and wrist joints of both hands. The vaccine was commenced on the following day. Swelling began to diminish on February 7th and had completely disappeared on March 18th. Pain became easier on February 16th and had completely gone on February 20th. The result was that the movements of hands and fingers were quite good. The temperature was normal on admission and remained so afterwards.

CASE IV.

Admitted on January 25th, 1917, with gleet and stiff and painful neck. X-ray examination on January 14th showed thickness of spinous process and also of body of second cervical vertebra. The diagnosis of gonococcal infection having been made, the vaccine treatment was begun on February 16th. On February 19th pain was easier, on March 5th movements of the neck were quite good, and on March 17th all trace of pain and limitation of movement had gone. The temperature was normal throughout.

CASE V.

Admitted February 1st, 1917, with purulent urethral discharge and some swelling and pain of the knee-joint. Vaccine treatment was commenced on the following day. The pain became easier on February 12th and had completely gone on March 1st. Swelling began to diminish on February 13th and had disappeared on March 1st. The result was that the joint was perfectly well. There was a slight rise of temperature for the first few days.

CASE VI.

Admitted February 1st, 1917, with swollen and painful right elbow, but no urethral discharge, though he had had gonorrhoea on January 19th, 1917. Vaccine was begun on February 2nd; three days later the pain was easier and the swelling began to go down. On February 10th pain had entirely gone. On February 16th the swelling had disappeared, and a week later extension and flexion of the forearm were almost complete. Temperature was normal throughout.

CASE VII.

Admitted January 1st, 1917, with gleet and some swelling of both knees and both ankles. Patient was much attenuated. Vaccine was begun next day. On January 14th the pain became easier. On January 16th the swelling began to go down, and next day both pain and swelling disappeared. The patient was then evacuated to England, as he was still very much wasted, and his legs were very weak. His temperature was normal throughout.

CASE VIII.

Admitted January 14th, 1917, with purulent urethral discharge. On January 26th some swelling and pain appeared in the left ankle. Vaccine was begun on February 6th. On February 9th the pain became easier, and the swelling began to go down. On February 12th the pain and swelling had gone. The result was complete recovery of the joint. The temperature was normal throughout.

CASE IX.

Admitted January 22nd with right epididymitis and some swelling and pain of the right knee. Vaccine was begun the same day. On January 30th the swelling began to go down. On February 10th the pain became easier, disappearing two days later. The swelling had gone by February 15th. The result was complete recovery of the joint. The temperature was normal throughout.

CASE X.

Admitted February 20th, 1917, with purulent urethral discharge, and some swelling and pain of the left knee. Vaccine was begun on that day. The swelling began to go down on February 28th, and the pain improved on March 11th; by March 26th both pain and swelling had gone. In the result the patient was still weak but able to walk, and the joint was freely movable. The temperature was normal throughout.

As regards local treatment of the joint every patient had rest and application of Scott's dressing.

The above-mentioned cases gave encouragement to continue with the sensitized vaccine, but it was thought desirable to try the administration of bigger doses.

On that account the following routine was adopted in the cases reported below:

1st day	100 million of gonococci.
5th day	200 " "
9th day	400 " "
13th day	600 " "
17th day	800 " "
21st day	1,000 " "
25th day	1,200 " "

And increasing 200 million every fourth day up to a maximum of 2,000 million.

CASE XI.

Admitted May 16th, 1917, with gleet, some swelling and pain of left wrist, and slight swelling of left shoulder with marked stiffness and restricted movement. Vaccine was begun the same day, and on May 23rd the pain became easier and the swelling began to subside. On June 6th the pain and swelling had gone. The result was that movements at the wrist were quite normal, and only slight restriction of movement remained at the shoulder. The temperature was normal throughout. In this case the local treatment was by ionization.

CASE XII.

Admitted April 14th, 1917, with purulent urethral discharge. On July 3rd some swelling and pain appeared in the left knee. Vaccine was begun next day. The pain became easier on July 13th, and the swelling began to subside on the 14th. The pain and swelling had gone on August 6th. In the result the knee was practically normal, though movement was somewhat restricted. The temperature was normal throughout.

CASE XIII.

Admitted June 11th, 1917, with purulent urethral discharge, and some swelling of the left knee. Vaccine was begun on July 11th, and the pain was easier two days later. The right knee developed slight swelling and pain on July 16th. By July 18th the left knee was greatly improved. On July 28th the right knee was free from pain. Two days later the left knee was better and all other joints were normal. Finally on August 18th all movements were normal.

CASE XIV.

Admitted June 15th, 1917, with purulent urethral discharge, well-marked arthritis of the left elbow with fluid, early arthritis of the right elbow, and pains in the right leg. Temperature 102° F. Vaccine was begun the same day. The pain was less on June 21st, and the swelling less on June 27th. The pain disappeared on July 10th, and the swelling on July 14th. A week later movements in the arms were normal.

CASE XV.

Admitted June 30th, 1917, with purulent urethral discharge, swelling and tenderness of left ankle and knee. Temperature 99.4°. Vaccine was begun at once; on the following day the right ankle was swollen. On July 14th both pain and swelling had diminished, and the ankles and knee were greatly improved on July 16th. By August 1st the pain had left the affected joints, the left knee was practically normal, the right knee normal, but the left ankle still slightly swollen. This patient showed marked reaction to the vaccine when he received a dosage of 1,200 million, after which he had transient pains in all his joints.

CASE XVI.

Admitted July 8th, 1917, with purulent urethral discharge and both knees swollen and painful. Temperature 99.6°. Vaccine was begun the same day, and the pain and swelling abated on July 13th. On July 18th the right knee was greatly improved; the left knee slightly improved. The next day there was slight pain in the right ankle, and on July 23rd the fingers of the left hand swelled. The right ankle was free from pain on July 24th. On August 15th the knee movements were practically normal, and on August 23rd the hand was better and the left ankle almost well.

CASE XVII.

Admitted July 23rd, 1917, with gleet, and swelling and pain of left knee, but no fever. Vaccine was begun the same day. The pain and swelling were less on July 28th. The knee was greatly improved on July 31st, and the pain had gone on August 16th. By August 20th the knee was practically normal in its movements.

The last six cases were all treated locally with Scott's dressing, lead and opium fomentations, and ionization.

From a consideration of these seventeen cases I feel justified in recommending the administration of sensitized gonococcal vaccine as a line of treatment worthy of trial in cases of acute and subacute gonococcal infection of joints.

The first case, as already stated, was given an auto-genous sensitized gonococcal vaccine, the micro-organism being grown from the fluid aspirated from the knee. All the other cases were treated with sensitized gonococcal

vaccine prepared from four strains of gonococci, all of which were obtained from urethral discharges. None of these strains was autogenous for any of the cases treated.

I have the impression that recently-obtained strains are best for this purpose, and endeavour has been made to avoid using gonococci which have been subcultivated for more than four months, the strains being discarded at the end of that period and younger ones employed. Four strains of gonococci have always been employed in the preparation of the stock vaccine.

In the matter of dosage the second routine has the advantage of being less troublesome for both patient and medical officer, and the results are quite as good as with the first routine; the second is to be recommended, though probably one might give even bigger doses with safety.

Only a few of the cases treated have shown any reaction after administration. Case xv showed the most marked reaction, and one or two of the others had a slight increase of pain in the affected joint or joints, which generally disappeared after a few hours.

I have to acknowledge my indebtedness to Captain C. Lundie, R.A.M.C., and Captain W. J. Ronan, R.A.M.C., for giving the vaccine an extended trial in their cases and for so kindly supplying me with the clinical notes. I must also thank Captain Billington, R.A.M.C., for his helpful suggestions when I began this work.

A NOTE ON MUSCLE NERVE TESTING DURING OPERATION.

By W. ROWLEY-BRISTOW, M.B., B.S.LOND., F.R.C.S.,

CAPTAIN R.A.M.C.(T.),

Surgeon to, and Officer in Charge of Electrical Department, Military Orthopaedic Hospital, Shepherd's Bush.

THE following is a brief account of the method adopted for the electrical testing of a peripheral nerve at the time of operation at the Military Orthopaedic Hospital, Shepherd's Bush.

It is necessary, in the first place, to emphasize the extreme importance of testing the excitability of the nerve in many cases, and that it is therefore essential that the surgeon should be prepared to do so in every case. If, on cutting down on the nerve, a complete anatomical division is found, with an end bulb on the proximal end and perhaps an inch or more of separation, there is no need to test the electrical conductivity of the nerve.

But very often this is not the case. The exposed nerve may show a thickened area with no anatomical division, and the question arises whether or no there is physiological conduction through this. It may be thought that a complete investigation of the case beforehand should suffice for diagnosis, but it happens sometimes that the notes of cases are not complete, and that the surgeon may not be fully familiar with the case. In any case, a diagnostic method as easily applied and as valuable as is that under discussion should always be made use of.

It is quite simple to test the conductivity of the nerve, and the result, coupled with a consideration of the history, will give a clear indication whether the lesion is recovering or not.

The relative rapidity of return of voluntary power and of faradic excitability (as ordinarily tested) after injury is not constant; sometimes the one and sometimes the other returns first. If the exposed nerve is stimulated faradio response in the muscles always precedes, in my experience, the return of voluntary power. It occurs so often that it may be regarded as a constant factor.

Illustrative Case.

Pte. H. Gunshot wound through neck, August, 1916.

There was a lesion of the fifth and sixth cervical nerves, with paralysis of the deltoid, biceps, and supinator longus muscles. The scars of entrance and exit were in the root of the neck.

The case was treated with the arm in abduction for five months, in order to relax the deltoid and biceps. As there was no evidence of recovery, exploration was decided upon. The fifth and sixth cervical nerves were explored in the posterior triangle, together with the upper trunk and its anterior and posterior divisions. Some scar tissue was dissected off during this exposure, and the nerves were stimulated. Faradic excitability was evidenced by contraction of the biceps, deltoid,

and supinator longus muscles, and the wound was closed. Two months later faradic response and voluntary power were regained in the paralysed muscles. The recovery was neither hastened nor retarded by the operation, in all probability, but the response to the test rendered further exposure unnecessary, and made the prognosis as to recovery favourable.

Testing is sometimes of use in another way when operating on cases in which there is much scar tissue and the anatomical relations of parts are disarranged. Any nerve or branch can be stimulated and defined with certainty by noticing the muscle or muscle groups which contract on such stimulation.

The Apparatus.

The apparatus required consists of (1) a faradic coil and metronome, and (2) electrodes and connecting cords which can be sterilized by boiling.

The only essential of the coil is that it shall yield a sufficiently weak current. The coil we use yields a current so weak that it can only just be appreciated when both electrodes are placed on the tongue. If the current is strong, the overflow to the muscles other than those which are being tested causes general contractions, and renders accurate observation impossible. This difficulty is commonly met with.

The metronome interrupter is the simplest method to adopt in testing. The metal probe is held in contact with the nerve, and at each beat of the metronome the electrical circuit is made or broken. The testing electrode has not to be moved, and an accurate observation is easily made.

The testing electrode, a long metal probe with a terminal at the end for the attachment of the connecting wires, is far simpler than the type sometimes employed, consisting of two platinum wires insulated in a glass handle. These dipolar electrodes are easily broken—for example, in boiling—and, moreover, great care has to be exercised that both points, which are close together, are making contact with the nerve at the same time. The metal probe electrode is absolutely simple, cannot get out of order, and there is no difficulty in being sure that it is making contact with the nerve.

The cords and connexions are all sterilizable by boiling. There is no need, therefore, to wrap them in towels and so waste time during the operation, and there is no risk of infecting the wound. The connecting cords can lie on the sterilized towels by which the field of operation is shut off without risk.

The secondary electrode necessary to complete the circuit is attached to any convenient part well clear of the site of operation. In testing the nerves of the arm, for example, it is attached to the foot.

Method of Application.

The nerve is isolated and the field of operation rendered dry by swabbing. A glass rod is passed under the nerve and the metal probe is placed in contact with the nerve. The core is fully withdrawn, one cell actuates the battery, and one layer of secondary is used (the studs for these adjustments are clearly marked on the coil), and the metronome is started. A normal nerve will be stimulated by this weak current, and the muscles supplied by it will contract at each beat of the metronome. If there is no contraction the current is strengthened by pushing in the core, and if further strength of stimulus is necessary by using two layers. Any current stronger than this is unnecessary, and will simply cause contractions in the surrounding normal muscles by leakage along the nerve sheath.

With the equipment advised and a nurse or assistant told off to work the metronome and turn on and off as directed, the testing takes only a minute or two.

As a point of interest and as showing how weak a stimulus is used the following fact may be noted: In stimulating the median nerve exposed in the arm, the muscles put into action vary according to the exact part of the circumference of the nerve which is stimulated. Thus the pronator radii teres or the flexors of the wrist, or the long flexors of the thumb and index finger can be made to react as practically pure and uncomplicated actions.

Incomplete Lesion.

In dealing with incomplete or partial division of a peripheral nerve it is sometimes necessary to suture part

of the nerve and to leave other fibres intact. An exact estimate of the extent of the paralysis is of value. Incomplete lesions are not uncommon in the cords of the brachial plexus, and are frequent in the sciatic.

Pte. J.; simple fracture of femur at the junction of the middle and lower thirds, complicated by complete paralysis of the muscles supplied by the external popliteal nerve and weakness of those supplied by the internal popliteal.

On exploration it was found that the lesion was situated at the entrance to the popliteal space and that the sciatic was not divided but existed as one trunk.

Faradic stimulation both at and above this point yielded no contraction in the external popliteal supply. By dissection the external popliteal element was freed and found to be totally divided, whilst a marked thickening of the sheath, in which were embedded fragments of bone, caused a thickened lump in the internal. This was all dissected off, and the nerve was again stimulated. As it responded it was proved that no damage had been done to the conducting power of the nerve during this extensive cleaning of the sheath.

Complete Lesions without Anatomical Division.

In such a case as the following the absence of faradic response, together with the length of history, indicated the necessity for excision and suture.

Pte. G.; gunshot wound of forearm, lower third, with paralysis of ulnar, intrinsic of the hand, and loss of sensation in the ulnar area. Exploration four months after the injury.

The ulnar nerve was exposed and found in anatomical continuity, but with a small hard nodule, the size of a pea, in the substance of the nerve. No faradic response was obtained by stimulation of the nerve trunk above the lesion. The nodule, which occupied the entire thickness of the ulna, was excised and end-to-end suture performed. Macroscopically there was no evidence of nerve fibres in the excised nodule.

EYE CHANGES IN TRENCH NEPHRITIS.

BY

J. KIRK, M.D. EDIN.,

LATE TEMPORARY CAPTAIN, R.A.M.C., AND SPECIALIST IN
OPHTHALMOLOGY, CURRAGEH AND MALTA COMMANDS.

DURING the spring of 1917 I had the opportunity, while on duty at Malta, of examining a series of cases of trench nephritis, or what is probably the more correct term, war nephritis. They were seventy or eighty in number, and all came in the same convoy from the Macedonian front. They were chiefly young active soldiers between 20 and 30, though they were a few older men among them. The history was generally the usual one of fairly severe exposure and strain, though not necessarily in the front line. Nearly all the cases presented the disease in a severely acute form, and on their admission were mostly seriously ill. At that time the fundi of a large number were examined, either by myself or by my colleague, Dr. Moffett. We found almost invariably marked retinal congestion, with large pulsating veins. There were no signs then, however, of any patches of exudation or nerve involvement. Some weeks later, however, on the examination of one or two patients who had complained of eye symptoms, we found present the more definite changes of nerve swelling, accompanied by patches of retinal exudation. We then decided to examine the whole series again, and by degrees this was done, with the following result. To make the points clear the cases may roughly be classified at the time of this examination (somewhere about three months from the onset of their illness) into three groups, A, B, and C.

Group A numbered about 21. They were all convalescent, presenting practically no symptoms except slight anaemia and debility. The urine was free from albumin, except for a very slight trace in a few. In only four of this class were retinal changes found, and they were slight in amount—a few small spots of exudation, a small punctate haemorrhage, a slight haziness of the disc edges, or a little oedema along the course of the veins.

Group B—a series of 20 cases who had not done so well as the others. Albumin was generally present, though in small quantity. There was breathlessness and slight oedema often. Of these cases, 8 showed minor retinal changes, with small exudation spots. One, however, showed much more marked changes, pointing to a fairly severe neuro-retinitis.

Group C, 13 in number, were severe cases in which the disease was still marked. They were suffering from

general symptoms, severe oedema with often a large quantity of albumin in the urine and sometimes blood. Of these 13, 4 showed very definite retinal changes and 4 changes of a slighter nature.

As far as could be ascertained, there were no signs of any other complicating disease, with the exception that several cases showed malarial infection. In none was there any history of previous kidney attacks. In 9 of the cases presenting the more severe retinal changes a Wassermann test was done, and in all of the 9 the result was negative.

Some points in regard to the fundus changes are:

1. That while the spots of exudation were generally in the usual situations—that is, near the disc and in the macular area—in no case was seen the typical silvery star-like figure of the chronic cases as figured in the textbooks.

2. Haemorrhage was not common. Those seen were of the small punctate variety, and not of the striate or flame-like character.

3. The optic disc was often affected, the changes varying from a definite swelling to slight wooliness and indistinct edges.

4. Small areas of oedema were noticed, especially along the course of the veins.

5. An important point was that in several of the series I was able to trace the gradual absorption of some of the smaller patches of exudation, and the healing process was very interesting to watch.

Summary.

To sum up the matter, I would say:

1. That in this disease the retina is very liable to be involved, although gross changes are not evident in the early stages, and latterly changes which had been present may have become absorbed.

2. That the pathology is probably an acute congestion resulting from some specific toxin, that the exudation which ensues is partly lymphoid and partly cellular in nature, and that this deposit probably clears up in the great majority of cases, without leaving any permanent results.

3. That the retinal changes do not affect the prognosis, except in so far that the severer these changes the severer the cases, in many instances, though by no means necessarily so.

4. That the condition is one which is probably allied to the acute retinitis of pregnancy, scarlatina, and acute uraemia, and should not be confounded with the retinitis of chronic kidney inflammation with its permanent changes in the retinal circulation vessels and tissues.

I have to thank my colleague, Dr. Elizabeth Moffett, for her help and assistance, and also the C.O. of Valletta Military Hospital, Lieut.-Colonel Slaughter, R.A.M.C., for his kind permission to publish these notes.

SYCOSIS AND OTHER CHRONIC STAPHYLOCOCCAL INFECTIONS OF THE SKIN, AND THEIR PREVENTION.

By H. G. ADAMSON, M.D., F.R.C.P.,

PHYSICIAN FOR DISEASES OF THE SKIN AT ST. BARTHOLOMEW'S HOSPITAL.

At the present time considerable numbers of able-bodied men become invalided on account of chronic staphylococcal infections of the skin. These infections include:

(1) Sycosis menti, and similar affections of other hairy parts, namely, the upper lip, the eyebrows, the eyelashes, the scalp, and the pubes and axillae; (2) chronic furunculosis; (3) chronic eczematized impetigo of the trunk and extremities.

The majority, probably all, of these cases could be avoided were the initial skin complaint correctly diagnosed and efficiently treated.

These staphylococcal infections may be all included under one term—impetigo of Boeckhart; and an important fact not generally recognized is that they always, or nearly always, arise as a secondary complication of another form of impetigo—impetigo contagiosa of Tilbury Fox—an affection which is comparatively easy to cure.

The distinctions between the two groups of impetigo—first clearly demonstrated by Sabouraud in 1900—are not

even yet sufficiently known, probably because they are not pointed out, or not pointed out sufficiently clearly, in textbooks devoted to diseases of the skin. The distinctive characters of these two kinds of impetigo may be summarized as follows:

Impetigo Contagiosa of Tilbury Fox.

This is a highly contagious skin complaint due to the *Streptococcus pyogenes*. The characteristic lesions are the amber-coloured stuck-on crusts, which are formed by the dried-up serum of vesicles or blisters. In other words, the lesion resulting from streptococcal invasion of the surface of the skin is a superficial blister, which contains clear serum, which so rapidly dries into a crust that the early vesicle is usually unobserved. If, however, we remove the crust with forceps, we see a superficial erosion, with an overhanging fringe of the horny layer of the epidermis, which has exactly the appearance of, and indeed is, the floor of a broken blister.

This streptococcal impetigo contagiosa is of very common occurrence among children of the poor in the form of a crusted eruption upon the face or scalp. It is seen sometimes, too, as an epidemic among public school boys as what is known as "serum pox." It not infrequently attacks the chin and cheeks of male adults as a result of infection while being shaved. It occurs also on the limbs and trunk as a complication of scabies. In soldiers it is seen particularly in these two latter forms, on the head and cheeks or upper lip, as a result of a visit to the barber, and on the limbs and trunk and sometimes the face, in association with scabies.

It is from these two generally easily cured forms of impetigo contagiosa that arise most of the incurable staphylococcal infections—sycosis, furunculosis, and chronic impetigo—which may be grouped together as impetigo of Boeckhart.

Impetigo of Boeckhart.

This is a staphylococcal infection of the hair follicles which results in the formation of perifollicular pustules. The pustules may be small and closely set on some hairy region, as in sycosis menti, or they may be larger, and scattered over the trunk and limbs, as in furunculosis. In contrast with the superficial vesicular lesion of impetigo contagiosa, that of impetigo of Boeckhart is a deeply seated pustule. The streptococcal invasion leads to a superficial serous exudation; the staphylococcal infection to an exudation of polymuclear leucocytes or pus cells, deeply in the tissues round a hair follicle.

Treatment of Streptococcal Impetigo.

In spite of the often formidable appearance of a streptococcal impetigo and of its tendency to spread rapidly, it is, on account of its superficial character, generally very easily cured by appropriate treatment. The staphylococcal impetigo, on the other hand, because of the deeply seated infection, is much more difficult to deal with, and many cases of long standing seem to be practically incurable. Herein, then, lies the importance of the early diagnosis and cure of impetigo contagiosa, since, as has already been said, nearly all, if not all, cases of incurable, or difficultly curable staphylococcal infections of the skin arise as a complication of uncured impetigo contagiosa. The usual sequence of events in these circumstances is as follows: A man gets a simple impetigo contagiosa of the chin and cheeks—superficial, amber-coloured, stuck-on crusts, which rapidly increase in number and extent. The eruption is perhaps diagnosed as eczema, or it is correctly diagnosed but not treated in exactly the right way, and as a consequence the eruption persists, and the vesicles and the crusted erosions become secondarily invaded by staphylococcus. The staphylococcus, once established, invades the hair follicles, and little follicular papules and pustules begin to appear. Soon the whole beard region becomes involved, so that every hair follicle is the site of a papulopustule, though the discharge from the conglomerated papulopustules often dries as a crust, which covers the chin and masks the follicular nature of the eruption. The condition is then that of sycosis menti, a most obstinate affection to deal with. The man remains under treatment in hospital for months, sometimes years, and has treatments by ointments, by vaccines, and by x rays. But the sycosis remains uncured.

In many instances the sycosis does not remain limited to the beard region, but attacks also the eyebrows and eyelids, the scalp and the upper lip, the pubes and the axillae, and a furunculosis of other parts of the skin, of the neck, or the trunk or the limbs may be added to his other affliction.

In the second type of case the man has scabies complicated by turbid vesicles on the hands and feet, and crusted patches on the limbs and trunk. On the buttocks there is often a more severe type of impetigo contagiosa—that is, ecthyma, in which the crusted erosion is converted into a shallow ulcer with inflamed base, and with or without a dirty-brown crust.

Most of these cases of impetigo complicating scabies yield in the early stage to the three hot-water and soft soap baths, and the three sulphur ointment applications of the treatment for the scabies. But cases not treated early and thoroughly may develop later a generalized eruption of boils—that is, a chronic furunculosis, or they may be converted by scratching into eczematized impetigo, with eczema-like, infiltrated, itchy, crusted areas on the limbs and trunk, which often resist all treatment.

The Treatment of the Initial Impetigo Contagiosa.

The whole secret of success in the treatment of the initial impetigo contagiosa is to remove first of all every trace of crust and every overhanging blister margin. This is best and simplest done by prolonged and frequent mopping with hot water. The patient is made to mop off the crusts by bathing the affected parts for half an hour two or three times daily. At the same time all crusts must be carefully wiped off with wool or picked off with forceps. Immediately after the bathing the eroded surfaces are mopped with lotio hydrarg. perchlor. 1 in 6,000, or with lotio cupri sulphatis 1 in 8,000; then an ointment (ung. hydrarg. ammon. chlor., gr. x ad 3j) is smeared on, to remain until the next mopping. When the impetigo complicates scabies and involves the limbs and trunk, it may be necessary to continue the hot baths beyond the three prescribed for the scabies treatment, and to substitute ung. acid. bor. for the ung. sulphuris after the third sulphur ointment application. Obstinate patches of ecthyma are best treated by complete removal of the crusts by repeated mopping with hot water, followed by careful and thorough application to the shallow ulcer of argent. nitratis gr. xv, spirit. aetheris nitrici 3j.

The Treatment of Staphylococcal Infections of the Skin.

This is a much more difficult theme. The once much-vaunted treatment by vaccines has not proved the panacea it was proclaimed. In quite early cases of staphylococcal infection it is, however, worth a trial, for here it does sometimes seem to give remarkably good results. But, while even in early infections its results are uncertain, in long-standing chronic sycoses and furunculosis it lamentably fails, and often does harm. The x-ray treatment of sycosis has given equally disappointing results. It is always possible, by complete depilation, with x rays, to produce what at first appears to be a cure, but almost invariably the disease relapses so soon as the hair grows again. We are generally compelled, therefore, to resort to the older methods of treating sycosis, and in cases where the infection is limited to the upper lip, to the "imperial," or to a part of the chin, cures may be eventually brought about by repeated depilation with forceps and applications of antiseptic ointments. The patient is taught to extract with forceps as many hairs as possible daily for weeks or months, and daily he rubs in an antiseptic ointment, such as ung. hydrarg. oleat. 5 per cent. or ung. iodox. But when the whole scalp, as is sometimes the case, or other extensive areas are involved, this treatment is impracticable. For very limited areas, as the eyebrows and upper lip, or imperial, an often completely effectual remedy is the application once or twice weekly of pure carbolic acid, carefully dabbed on with a match stick or very small swab of absorbent wool.

In the treatment of furunculosis, vaccines of staphylococcus may be given in doses of 50 to 150 million weekly. Larger doses are better avoided, as they often lead to over-stimulation and an exacerbation or spread of the infection.

Much may be done to prevent fresh infections by

constant change of linen; by frequent baths (baths of copper sulphate 3ss to 20 gallons); by antiseptic lotions mopped over the whole area involved (lot. hydrarg. biniodidi 1 in 10,000); and by individual attention to each boil. The earliest lesions should be painted over with a drop of pure carbolic acid. Larger boils may be fomented, but they may generally be made to dry up rapidly by the following method: Into the central point of the boil a pointed match stick which has been dipped in pure carbolic is gently inserted. This smarts at first, but the carbolic acid soon numbs the pain. The match stick is again dipped into the carbolic and put more deeply into the boil. It will then be found that an opening has been made and that the pus can be gently squeezed out. A small wad of absorbent wool is now tightly wound round the ends of a fine forceps and dipped into pure carbolic. The carbolic-soaked wad is then used to thoroughly mop out the cavity of the boil, and finally some pure carbolic is painted over the surface of the boil and a piece of dry wool put over it. In twenty-four hours the boil will have almost subsided, and in a day or two it will have disappeared. By diligently attacking every fresh boil in this way we may succeed eventually in stamping out the infection, but disappointment sometimes follows by a recrudescence of crops of boils at a later period.

The treatment of chronic eczematized impetigo of the limbs and trunk, which is so often a sequel of scabies complicated by impetigo contagiosa and not properly treated in the beginning, is even more unsatisfactory than that of a mere furunculosis; for the scratching induced by the itching not only keeps going the eczema, but leads to fresh crops of follicular pustules and boils. Sometimes these chronic eczematoid impetigos yield to an ointment of pyrogallie acid gr. j in ung. zinci oxidi 3j, or to applications of small doses of x rays. But more often they persist in spite of the treatment, to the despair of the medical officer.

The early recognition and right treatment of the streptococcal impetigos—impetigo contagiosa of Tilbury Fox—is, then, the only sure method for the elimination of these obstinate and often incurable staphylococcal infections which arise as a sequel to the initial and more easily overcome streptococcal infection.

THE TREATMENT OF PSORIASIS BY X-RAYS AND CHLORINE IONIZATION.

By CHARLES E. DE SILVA, M.B., B.S. DUBLIN,
M.R.C.S., L.R.C.P. LOND.

CONSIDERING the obstinate, rebellious nature and the chronic and recurrent course of psoriasis, its depressing effect and the despair of the patient are not at all surprising. Nor is his lack of patience, perseverance, and co-operation in carrying out a prolonged, tedious, and disagreeable course of treatment astonishing.

Arsenic is found to be the most valuable and the most constant in its effects. It is the favourite drug given internally in increasing doses for a long period. Its prolonged administration is, however, attended by remote ill effects and dangers, such as gastro-intestinal and nervous disturbances, general pigmentation of the skin, keratosis of the skin (especially the palms and soles), callosities, warts, horny formations, and even cancer. Chrysarobin is the most powerful and generally used local remedy. It stains both the garments and the skin and excites dermatitis of the surrounding skin and severe conjunctivitis if the eyes are touched. It is, besides, a very disagreeable application which necessitates confinement to bed or to the house, and necessarily interferes with the patient's occupation.

In the following case the rapid involution of the eruption, the painless, clean, and agreeable nature of the treatment, which does not interfere with the patient's occupation, and takes up only a few minutes to half an hour a week, and its freedom from remote ill effects and dangers when properly applied, are worthy of attention.

A boy, aged 15 years, of otherwise good general health, in the summer of 1914 presented a dry, scaly, papular eruption on the palms, back of the hands, and webs of the fingers—more on the left side. There was no itching. There was some thickening of the skin of the left palm. With the advent of winter the

eruption was said to have faded away gradually, but the skin of the left palm remained thick, and showed a tendency to scale.

In the spring of 1915 the eruption gradually reappeared in a worse form on both hands. The patches were sharply defined, slightly elevated, thickened, and infiltrated. The dry, scaly, and imbricated papular eruption was growing peripherally. There was marked keratosis of the skin of the left palm. The scales were whitish and greyish. There were no vesicles or pustules. The dryness was very marked even in the fissures of the affected skin. There was no pain, itching, or other subjective symptom. Ointments, intestinal antiseptics, and aperients were given without any benefit. No arsenic was given. X rays were applied in September, 1915, with marked benefit. Four mild doses were given at weekly intervals. There was a retrogression of the eruption after the first application of the rays. The lesions yielded quickly to each exposure, and eventually disappeared after the fourth dose, but the skin remained somewhat thick and hard.

The eruption recurred in the spring of 1916. It came on gradually, as in the previous year, almost on the same sites, and was of the same character. Keratosis of the skin of the left palm was well marked. The patches gradually disappeared again after three small doses of x rays, given at weekly intervals in August, 1916. A week after the last treatment there was no trace of the eruption, and only a slight pigmentation was left, but the skin of the left hand was not quite soft and normal. Another mild dose of x rays was given about a month after the third dose. The condition of the skin improved after this, but it was not quite normal, and treatment was discontinued. No arsenic or internal medicine was given, nor was anything applied locally.

A similar recurrence of the eruption gradually set in in April, 1917, almost on the same sites, and of the same character. The patches on the right hand were larger and the keratosis of the skin of the left palm was more marked. No x rays were applied this time. On June 11th chlorine ionization was given to both the hands. Within a week the hyperaemia and scale formation became much less, and the skin was softer and more supple. Some of the fissures healed. The second treatment was given on June 17th. Within the next week all the fissures healed, the scaling was very slight and the skin was much softer. The third treatment was given on July 1st. Within a week the scaling entirely disappeared, and all inflammatory symptoms subsided. Healthy skin was forming in place of the portions that had peeled off. The skin of the left palm was nearly normal. By July 8th there was no trace of the eruption. No pigmentation occurred as under x-ray treatment. The skin of the left palm though quite soft was yet a bit thicker than normal. The fourth and last treatment was given on this date.

In this case the lesions were on the palms and back of the hands, which usually escape. There were no patches anywhere else. Keratosis of the skin of the left palm was not due to arsenic, as it was not taken at any time. Another unusual feature was the recurrence in warm weather. Usually the eruption improves markedly in warm weather and gets worse in cold. The beneficial effect of sunlight, the advantages of a permanent transfer to a warm climate, its less common occurrence in warm climates and in exposed parts, have been recognized, and point to seasonal influence as a powerful and important etiological factor.

Autointoxication due to poisons manufactured by the body as the result of defective metabolism, altered gland secretion, or absorption from the alimentary canal owing to defective digestive processes, appears to be the immediate and primary causative factor. The part played by the nervous system seems to be secondary, as does that of pathogenic organisms, to the toxæmia, which poisons and damages the epidermic cells and prepares the "soil" for successful parasitic invasion, as evidenced by the grafting of other lesions on patches of psoriasis.

Chlorine ionization is, I believe, more efficient than x rays. It is quick, and has the great advantage that the sittings can be continued as long as it is necessary without any ill effects whatever, whereas the application of x rays must necessarily be limited. The dose of x rays should be just sufficient to stimulate but not to injure or destroy the skin. Therefore x-ray treatment has to be stopped before the involution of the eruption in many cases.

In the local treatment of psoriasis and other diseases the electro-ionic method offers facilities which no other except x ray treatment affords. It allows us to introduce into each cell, impermeable to most remedies, a whole series of ions and to obtain different actions to the desired degree and depth. Ointments, liniments, and lotions act only superficially, and only an infinitesimal fraction can penetrate even into the deeper strata of the epidermis. The skin and the surface of wounds are, with the ordinary means of application, impermeable to powerful alteratives, strong antiseptics and coagulators of albumin, which

electrolysis readily introduces to whatever depth one wishes, through the skin and deeper tissues to joints even, and in sufficient quantity to produce the desired effect of stimulation, paralysis of function, or death of tissues.

Local ionic treatment could, with advantage, replace general treatment in many conditions. Medicines introduced into the stomach or subcutaneously enter the circulation, are added to the ions of the organism, and are eliminated after transient action; whereas by electrolytic introduction the ions are substituted for the ions of the organism and are not introduced into the circulation, but into the plasma of the cells which retain the ions for a long time and ensure efficient and lasting action on the tissues, which, moreover, get flooded with blood determined to the part by the vasomotor paralysis induced over the whole surface of introduction, lasting for several days. This action could be kept up by weekly sittings.

In x rays we have a more powerful weapon, which must, however, be wielded with greater care. The action of x rays is doubtless purely local, but as to its precise character there is still much to be learnt. The rays modify the electrical equilibrium of the tissue molecules, bring about chemical changes in the cells, and affect the vascular system. In small doses x rays produce at first a passing active hyperaemia, and then a lasting passive hyperaemia, stimulating the nutrition of the tissues, and causing the absorption of inflammatory products. They restore healthy metabolism and exert an antitoxic effect. In large doses their action is destructive. This disintegrating action is usually limited to certain elements of the skin, and is to be carefully avoided, except in a few special cases.

No other treatment can compare with these two most valuable and powerful methods, properly applied, for efficiency, rapidity, perfection of results, and absence of pain, where local treatment is indicated in any morbid condition. Moreover, their application is clean, agreeable, convenient, and cheaper in the long run.

ACIDOSIS AS A POSSIBLE CAUSE OF CERTAIN SYMPTOMS IN DIPHTHERIA.

By B. A. PETERS, B.A., M.D., B.C., D.P.H. CANTAB.,

MEDICAL OFFICER IN CHARGE, HAM GREEN SANATORIUM AND HOSPITAL, BRISTOL; LECTURER ON INFECTIOUS DISEASES, UNIVERSITY OF BRISTOL.

If severe cases of diphtheria do not receive antitoxin before the third or fourth day of disease death may occur on the fifth to seventh day from an overwhelming toxæmia with signs of heart failure. In a large number of late cases temporary improvement follows rapidly on administration of serum, the throat cleans, the patient is able to take a fair amount of food, and appears to be convalescent. About the tenth to twelfth day the complexion assumes a slightly dusky pallor, food is refused, and vomiting occurs. The vomit at first consists of food, but later becomes like coffee grounds. The patient vomits five or six times a day whether food or drink is given by the mouth or not. The heart's action becomes weaker and the pulse more feeble by slow degrees, until by the third day of vomiting the pulse is imperceptible at the wrist, the extremities become pale and cold, the urine is greatly diminished in quantity, the face assumes an earthy pallor, the liver may be enlarged, sometimes severe epigastric pain is present, occasionally, in older patients, a fear of impending death is present; the consciousness is maintained to the end, which is preceded by a short convulsion.

In nine years' experience in a large fever hospital I have never seen a case recover in which this condition is established, except one treated in the way to be described. These cases are described in the textbooks as suffering from late heart failure, but, from careful observation, the failure of heart, circulation, and kidneys appears to follow the onset of vomiting. The numerous cases which show feeble heart and circulation after diphtheria usually recover if vomiting is absent, except those which die from acute intoxication in the first few days.

All drugs have proved useless to check the vomiting. The administration of adrenalin, pituitrin, and salines by rectum or subcutaneously, and the stoppage of all food by

mouth slightly prolongs life, but does not stop the vomiting nor preserve the patient.

As certain cases present some features resembling the symptoms described as acidosis due to delayed chloroform poisoning,¹ a trial of the effect of the administration of 30 to 35 grams of sodium bicarbonate a day in 2 per cent. solution, by rectum and subcutaneously, was made on a patient showing this condition. This patient stopped vomiting within twenty-four hours, and after a prolonged convalescence recovered. Encouraged by this result, a daily analysis was made of the total urine of seven of the more serious cases for evidence of acidosis. Examination of total acidity, total N, total NH_3N , relation of NH_3N to total N, the quantity of acetone and oxybutyric acid, was made daily. Of these cases, five recovered without vomiting, two died with vomiting symptoms. In these last two cases there is, unfortunately, a gap in the records between their first admission and the onset of vomiting. The first five cases excreted daily acetone varying from 0.040 gram to 0.622 gram, and oxybutyric acid from nil to 1.1 grams. $\frac{\text{NH}_3(\text{N}) \times 100}{\text{Total N}}$ varied from 7 to 15 per cent.

The acetone bodies diminished within three days after serum to a mere trace, and $\frac{\text{NH}_3(\text{N}) \times 100}{\text{Total N}}$ to below normal.

The disappearance of acetone bodies took place in spite of the fact that the patients were only having milk; and, in fact, the case showing the highest proportion of these bodies had been having a considerable amount of carbohydrate food in addition before admission, so that their presence was apparently not due to mere starvation. The complete figures for the two vomiting cases are given below.

CASE VI.—The patient, aged 6, was admitted on the third day of disease; antidiphtherial serum, 16,000 units, given. On the tenth day vomiting occurred five times. On the eleventh day the patient was given 36 grams of sodium bicarbonate; there was no vomiting. The following day 16 grams of sodium bicarbonate were given; no vomiting. Death took place on the fourteenth day.

Analysis.

Day of Disease.	Total Urine.	Acidity.*	Total Acetone.	Total Oxybutyric Acid.	Total N.	Total NH_3N .	$\frac{\text{NH}_3\text{N}}{\text{N}}$
3-4	c.cm. 525	60	gram 0.026	gram Nil	gram 2.2	gram 0.21	10%

11-12	772	22	0.254	Trace	2.5	0.029	1.9%
12-13	630	22	0.283	Trace	2.7	0.052	2%

* Equivalent to c.cm. N/10 acid per 100 c.cm. urine.

CASE VII.—The patient, aged 7, was admitted on the fourth day of disease; the case was a severe one. Antidiphtherial serum, 20,000 units, was given. Vomiting occurred three times on the ninth day, and also on the tenth; on this day 22 grams of sodium bicarbonate were given. No vomiting took place on the eleventh day; a further dose of sodium bicarbonate, 36 grams, was administered. Death occurred on the thirteenth day.

Analysis.

Day of Disease.	Total Urine.	Acidity.	Total Acetone.	Total Oxybutyric Acid.	Total N.	Total NH_3N .	$\frac{\text{NH}_3\text{N}}{\text{N}}$
9-10	c cm. 510	198	gram 0.51	gram 0.33	gram 3.2	gram 0.45	14%
10-11	360	37	0.41	0	3.3	0.21	7%
11-12	330	37	—	—	—	0.3	—

In Case VI acetone appeared to be washed out of the tissues by the increased urine. In Case VII this was not evident. From all these analyses there is no greater indication of acidosis than is present in many pyrexial conditions, except in the failure of a large amount of soda to render the urine alkaline. In fact, in Case VI the acidity was actually increased by 36 grams of soda. Cushny² notes that 12 to 15 grams is sufficient to render an adult's urine alkaline. It is probable that most of the soda is fixed by the proteins of the tissues. The small increase in acetone (from diacetic acid) only accounts for a negligible

amount. Considering that a diabetic may excrete up to 10 grams daily⁴ of acetone bodies without symptoms, these acids cannot account for the symptoms in diphtheria.

No lactic acid was found in the urine, and in Case VII the Cl as NaCl diminished from 4.5 grams to 2.05 grams between the tenth and eleventh days. The administration of the alkaline liquid rendered the patients oedematous, a condition not seen in those dying naturally with these symptoms, so apparently some of the fluid administered is poured out into the tissues. In each case the soda diminished or stopped the vomiting. The vomit remained as clear fluid and did not become like coffee grounds, and only contained 0.07 per cent. total acids (as HCl) to phenolphthalein.

If there is a real acidosis it might account for the symptoms, as Crile³ states that acidosis exhausts the adrenals, and the prostration, weakness of the circulation, and vomiting resemble the symptoms caused by adrenal failure in Addison's disease.

These investigations, extending over a year, are published with reluctance, as being very incomplete, but they cannot be completed as I am proceeding on military service, but on the original hypothesis prophylactic measures have been adopted which have given most encouraging results in the prevention of these symptoms. Every severe case coming under treatment late during the past eleven months has been treated at once with 10 to 15 grams of sodium bicarbonate a day for several days in divided doses by the mouth, in addition, of course, to full doses of antitoxin.

The number of cases admitted was 290; 52 were severe late cases (third day or after), and of these 11 died from all causes, including 5 within forty-eight hours of admission, and 3 from bronchopneumonia following laryngeal diphtheria; this leaves only 3 deaths from heart failure. Not one of the whole 290 cases had any vomiting, and many unexpected complete recoveries have taken place. The mixture given is—

Sodium bicarbonate	2 grams
Potassium bicarbonate	0.5 gram
Magnesium carbonate	0.5 "
Aq.	ad 30 c.cm.

Every four hours.

It appears to alter the toxic pallor to a more healthy tint, and increases the urinary secretion and diminishes the albuminuria.

Conclusions.

1. Some of the symptoms in vomiting cases of diphtheria may be due to a previous acidosis causing adrenal exhaustion.
2. These symptoms are not prevented by antitoxin if the patient does not receive it by the third or fourth day of disease.
3. The administration of large amounts of alkali to cases showing these symptoms diminishes or stops vomiting, but does not usually save the patient. The administration of 10 to 15 grams of alkali daily for several days from the earliest possible moment, with full doses of antitoxin, appears to prevent the onset of these symptoms.

Analysis.—Methods used: Acidity, neutralization in presence of neutral potassium oxalate and phenolphthalein. NH_3 , formalin method. Total N, Kjeldahl's method. Acetone and oxybutyric acid, Shaffer and Mariott. NaCl, by Volhard's method.

SEVERAL leading physicians of Rio de Janeiro have taken steps for the establishment of model sanatoriums in different regions of Brazil. The first is to be erected among the Itatia hills near the capital.

SURGEON-GENERAL BRAISTED, of the United States navy, in a recent report to Secretary Daniels, states that typhoid fever and other infectious diseases have been practically extinguished in the service by modern methods of prevention. Notwithstanding the vast increase in the personnel since the entry of America into the war fewer than ten cases of enteric have been reported in that period. The only diseases that cause any trouble at present are those due to infection through the respiratory passages, especially mumps and measles; and in all these the death-rate is very low.

A SIMPLE METHOD OF MECHANICAL FIXATION FOR FRACTURE OF LONG BONES.

By JOSEPH E. ADAMS, M.S.LOND., F.R.C.S.ENG.,
CAPTAIN R.A.M.C.(T.).

SURGEON WITH CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL, ETC.

The methods commonly employed in the operative treatment of fractures are all more or less laborious, and although the results amply justify the necessary expenditure of time and trouble, it appears to me that the methods of carpentry as exemplified by the use of plates, bolts, and screws, require modification in their application to a surgical problem.

The use of a bone graft may be more strictly surgical, but it is certainly laborious even with electrical saws and similar apparatus at the surgeon's disposal. Simplicity in all operative procedures is greatly to be desired, for, when the technique of an operation is easy, the risks of failure are correspondingly diminished. In the case of broken bones it is also most desirable to have a method of fixation applicable to compound as well as simple fractures, and it is the former which in reality present the more difficult problem. Bone grafting in the presence of sepsis is always doomed to failure, and the use of screws is condemned because they carry infection before them into the substance of the bone, they become loose, and they may soon fail to hold a plate in position. It is generally held also that whilst metal plates applied to fractures tend to delay bony union, their function is fulfilled if they hold the fragments in good anatomical apposition during the healing process. It is urged, on the other hand, that the bone graft promotes bony growth, and therefore hastens union. To my mind, the explanation lies in the fact that the graft is used as a wedge to press bony surfaces together, whereas the plate tends to press itself against the bone, and bone to bone is obviously essential for rapid union.

The bone clip of which I give an illustration is designed to partially encircle the fragments and to press them together and thus favour rapid healing of the breach in bone tissue. It is made of tempered spring steel and the upper half of Fig. 1 shows its application in the case of

FIG. 1.

FIG. 2.

an oblique fracture, drawn from an actual specimen. In the lower half of the diagram is seen a clip with a metal flange, designed for the treatment of a strictly transverse fracture, secured by means of a second clip. These clips exercise continuous elastic pressure on the fragments of bone within their grasp and the size selected must be proportionate to the size of the bone operated upon. It is not intended that more than two-thirds of the circumference of the bone should be grasped by the clip. The strength of the spring is quite sufficient to counteract laterally acting forces tending to displace the fragments, and the teeth by which the bone is gripped will resist a force acting in its long axis. All that is necessary after the clip is in position, therefore, is sufficient immobilization by splintage to avoid violent movement and no extension need be applied to the limb. A transverse fracture, as I have found from recent experience, can sometimes be quite well secured by a single clip of the ordinary dimensions, or by one which is made especially wide. It is to be admitted that in the case of a true transverse fracture one does not get the ideal pressing together of the raw surfaces of bone, but this merely indicates the need for longer immobilization of the limb before union can be expected. As a matter of fact the fractures which call for mechanical fixation are rarely absolutely transverse.

The technique of this method of operating is extremely simple, and the only special instruments required in addition to the clip and the introducer are two pairs of Lane's curved bone retractors.

The steps of the operation are as follows: A linear incision is made down to the seat of injury, the long fragments are identified, and the way in which they require to be fitted so as to obtain perfect apposition is noted. In oblique fractures forcible extension with rotation of one or other fragment is usually satisfactory, but with jagged and irregular bone surfaces protrusion of the ends through the wound and then dovetailing them into position by manipulation is the better plan. The muscles are first retracted by Lane's instruments and pushed out of the way, and then the curved portion is passed over the bone between it and its separated periosteum, this separation being largely the result of the fracture rather than purposely carried out by the surgeon. In this way four retractors are placed in position, one on each aspect of each main fragment, in the same way as a tyre lever is passed between a tyre and the rim of a motor wheel; the two pairs can be pushed away from one another along the bone until a sufficient subperiosteal space is exposed for the application of the clip. The bone ends must then be got into perfect apposition and the clip lifted from the instrument table by passing the prongs of the introducer through the small loops at its ends. Nothing which will be introduced into the wound need be touched even by the gloved hand, and the introducer is made of considerable length so that the clip is easily lifted and opened without coming near the surgeon's hand. The next step consists in passing the open clip round the bone at the seat of fracture and adjusting it until it holds the fragments in a firm grip; it is important not to dislodge the introducer until the best position has been obtained, and then a tap with one of the retractors on the side of this will readily disengage the prongs from the loops of the clip, whose spikes give it a firm hold on the partially encircled bone. The strength of this method of fixation can immediately be tested by moving the limb, and the security of the joint will at once become apparent. The spikes or teeth obviate the need for any screws or nails to affix the clip to the bone, and they leave a small space between the metal and the osseous tissue, so that pressure necrosis is hardly to be feared. Even in the femur of a young child they do not tend to bury themselves in the bone, and thus bring the clip into complete apposition with the bony surface. This is an important point, which has a bearing on the removal of the clip, if this should be called for at a later date.

The accompanying diagram shows the operation completed as far as the bone is concerned.

FIG. 3.

Since I first described this method of operating on fractures I have gained further experience of its value and am convinced of its suitability in a large number of compound fractures and even gunshot wounds, provided that the treatment is adopted at the outset. I have recently operated on about six cases of simple fracture of the femur at the East London Hospital for Children, and the results have been most gratifying, for in all but one perfect results, functional and anatomical, were obtained in about four weeks, with no shortening. In the exceptional case I have to admit that suppuration occurred, and this has delayed union by a few weeks, and has, up to the date of

writing, caused difficulty in securing movement at the knee-joint, but it has not affected the satisfactory alignment of the femur, and the experience gained by what I admit to be due to some error of technique has emboldened me to extend the use of the clip to the treatment of compound fractures. I may add that this case was a T-shaped fracture at the lower end of the femur, which is a type notoriously difficult of treatment. By frequent examination of these cases I have found that the presence of suppuration appears to double the time for firm union to take place, and in this particular case the bone was solidly united at the end of four weeks, whereas in all the others no rocking at the site of fracture could be obtained a fortnight after operation. Naturally the amount of callus formed in compound fractures is excessive and the healing that one obtains is of the "third degree," comparable to that seen in a septic wound of soft tissues. In the process of healing by first intention of a superficial wound the amount of granulation tissue is limited to the line of the scar, but this result is only secured by accurate apposition of the edges of the wound, which, by suture, are actually pressed together, and I claim that by the use of such elastic pressure as is provided by my bone clip a similar result is achieved, and healing of the fracture occurs by first intention by proliferation of bone cells and not by ossification of callus. It is well known that where there is perfect apposition of the fractured surfaces there is little or no callus formation, but it appears to me that we have been too long content with secondary union of bone, and that in all probability the period of healing in a fracture can be very materially reduced in many cases by operative treatment.

While admitting that these clips naturally fit best over bones with a circular contour, such as the femur, I have found them of considerable service in fractures of the tibia and have used them for difficult oblique fractures which could not be reduced by manipulation. In a recent compound fracture of the tibia, which failed to unite after several weeks' treatment by splintage and the use of a Steinmann's pin to secure extension of the lower fragment, the clip was successfully applied, and was removed at the end of about four weeks, when solid union had been secured, and the small granulating wound which had been present healed rapidly. As to the removal of these clips, I have devised no special instrument for the purpose, but I have had the introducer made in two pieces, so that each prong can be inserted in one of the loops and the instrument locked in a similar way to that in which mid-wifery forceps are applied. As a matter of experience, however, it is difficult to find these loops without opening up the wound considerably, and I have found that the point of one of the Lane retractors can be used as a lever to lift up the spring and dislodge it from the bone. Except in the case of compound fractures, of course, their removal will seldom be required.

In considering their applicability to the treatment of compound fractures, I wish to lay emphasis on the fact that no screws are required, and therefore there is no penetration of even the cortex of the bone, and very little stripping up of the periosteum is needed to secure a sufficient area of bone for the adjustment of the clip. When once they are placed in good position they grip surprisingly firmly by their small teeth; they act automatically in the case of oblique fractures in securing firm contact of the bony surfaces and withstanding displacement of the fractured ends. As I have already mentioned, the introducer should not be removed until perfect apposition and security have been obtained. I have recently employed one of the flanged clips in the case of a transverse fracture of the femur in a child, the flange being secured to the upper fragment with a clip having no teeth, and have been agreeably surprised by the firm hold obtained, seeing that the operation was not done until three weeks after the injury, when there was already some union in bad position with an inch overlap.

The most important, and unfortunately the commonest, type of compound fracture with which one has to deal at the present time is that due to gunshot wound, and I am convinced that these clips are worthy of trial in cases of this type, selected with due reference to the accessibility of the bone ends, if applied within a short time of the receipt of the wound. They are not open to the same objections as Lane's plates, in that they are not likely to carry infection before them and produce extensive osteitis. In my

experience, they are calculated to hasten the repair of the fractured surfaces even in the presence of infection, and I do not think that the treatment of the wound by Carrel's or similar methods would in any way militate against their efficiency as an internal splint. That such an internal splintage for the treatment of gunshot wounds of the femur and the bones of the upper extremity is desirable must be obvious to any one who has had to do with the compound fractures of the present war with their tendency to angular deformity, their shortening, and the disability of adjacent joints due at the same time to the necessity for prolonged splintage and the imperfection of every kind of external splint. It is idle to deny that these splints all possess drawbacks, and the simple explanation of their inefficiency is that we do not obtain sufficiently rapid union of the bone, but if care is exercised in the selection of cases and such clips are applied at the first dressing under anaesthesia, I believe our end results can be improved. Oblique fractures are obviously most amenable to this method of fixation, but I do not think the existence of comminution is any bar to success, and this type of fracture is much more common than the transverse. When there is a considerable gap in the bone some form of external extension apparatus is clearly required if the normal length of the limb is to be retained, and clips are not suitable. In compound fractures they should be removed as soon as the bone is solid enough, for otherwise they might be the cause of a persistent sinus.

The necessary apparatus has been made for me by Messrs. Lewis and Sons, Westmoreland Street, W.I., and one introducer suffices for all sizes of clips, since the prongs can be separated from contact up to three inches. The clips are made of spring steel in diameters ranging from half an inch to one and a half inches with quarter-inch increments. Those suitable for oblique fractures are provided with teeth turned over from the edge by which they grip the cortex of the bone, but I have found that in the case of the flanged clip for transverse fractures the flange is best held in contact with the bone by a clip without teeth so that it rests close against the bony cortex, after passing over the steel flanges. It is desirable always to use the smallest clips which will embrace the bone so as to secure the maximum degree of elastic pressure, and, at present, they are made of the lightest steel which will stand the necessary strain. It is desirable to open the clips with the introducer slowly and gently since with all their tempering they are apt to be slightly brittle.

Owing to difficulty in producing skiagrams satisfactorily at the present time, I regret that I am unable to illustrate this article with examples of cases operated upon, but I hope to do so at a later date. One of the satisfactory features of the operation is that in a straightforward case of simple fracture it can all be done easily in half an hour. In applying them to compound fractures where the bony surfaces lie already exposed in the wound the necessary steps would only add a few minutes to the length of the operative procedure.

REFERENCE.

¹ *Lancet*, May 12th, 1917, p. 725.

ACCORDING to a statement recently made by the New York State Department of Health, during the first nine months of 1917 motor cars caused 775 deaths in that State, being more than the number due to typhoid and scarlet fever taken together. In September such accidents were responsible for 155 deaths, more than the combined mortality from murder and suicide. The number of deaths caused by motor cars exceeds the number for the corresponding period of any previous year.

SWITZERLAND is believed to be one of the countries most afflicted with cancer. The Association Suisse pour la Lutte contre le Cancer has undertaken to collect statistical and clinical notes as to the most frequent localizations of the disease. Cancer of the breast, the increase of which is particularly notable, has been chosen as the first subject for investigation. The inquiry will be directed to the influence of lactation, inflammatory affections, and the pre-existence of mastitis, fibro-adenoma, and cysts, and of operation on prognosis in general and the formation of metastases in particular. Other points are the value of x-ray, radio-active, and other methods of treatment. All practitioners in Switzerland are invited to supply information as to cases treated by them from 1911 to the end of 1915. A special appeal for help in the inquiry is made to the surgical staff of hospitals and to pathological institutes.

Lectures

ON

THE ANATOMICAL AND PHYSIOLOGICAL PRINCIPLES UNDERLYING THE TREATMENT OF INJURIES TO MUSCLES, BONES, AND JOINTS.

GIVEN AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, NOVEMBER-DECEMBER, 1917.

BY

PROFESSOR ARTHUR KEITH, M.D., F.R.S.,
CONSERVATOR OF THE MUSEUM.

V. THE BEARINGS OF MARSHALL HALL'S DISCOVERIES ON ORTHOPAEDIC PRACTICE.

WHEN Marshall Hall first announced his discovery of reflex action, at a November meeting of the Zoological Society of London in 1832, he was a man of 42, a consulting physician with a considerable practice in London. He was born of a Saxon Midland stock—with an infusion of that hybrid strain which reached England through Normandy. His father was a cotton spinner and bleacher near Nottingham, the first in England to use chlorine for bleaching cotton. Marshall, at the age of 15, was apprenticed to a chemist or druggist in Newark, but in 1809, four years later, he became a medical student at Edinburgh, where he spent five years, three as a student and two as a resident in the Infirmary. After two years as a physician in Bridgewater and eight in Nottingham, he settled in London in 1826.

In the course of experiments on the circulation in capillaries he made a chance observation which directed his attention to the nature of the functions of the spinal cord. He had cut off the tail of a salamander, and happening to touch its skin observed that there was a quick movement in response. That response Marshall's predecessors had often seen happen, but it immediately excited his attention because it was taught in his time that a muscle could be stimulated to action in three ways only—either by touching or stimulating it directly, or by stimulating the nerve, or by a volitional stimulus from the brain. He knew that the movement he had evoked in the salamander's tail was due to none of these three causes; there must be a fourth way of calling muscles into action, and, as was his wont with exceptional cases, he followed up the clue. He destroyed the part of the spinal cord which lay in the detached tail, and found, on touching the skin, no movement could be elicited by touching the skin. He thus was led to suspect that in the spinal cord there resides a power, or mechanism, for the production of such movements as he had witnessed in the salamander's tail. To test his guess he took a snake and cut its spinal cord across, just behind the head, thus separating the brain, the recognized centre of muscular machinery, from the body. The snake remained perfectly still until he touched it, or a puff of wind struck it, or until the table was struck on which it lay, and then the snake moved and kept moving until he wrapped it in cotton-wool and thus brought it to a standstill by protecting it from all external stimuli; so soon as it was brought to a standstill and its skin was protected all movements ceased. He then cut off the head of a turtle, and found that on touching the nose, which he knew from Bell's teaching to be a respiratory area, the floor of the mouth executed the respiratory movements which occur in one phase of breathing in turtles, but that when he destroyed the medulla oblongata, he could no longer elicit the respiratory act. He concluded that when the nose was stimulated by touch, a message was carried to the medulla by the fifth nerve, and therein a centre excited another message which was reflected along the motor nerves which control the muscles of the mouth and throat. He pictured in his mind an arc of nerves, and recognized that a stimulus was necessary to produce the reflected or reflex muscular act.

He then exposed the spinal cord of the headless turtle; he touched the spinal cord with a needle: the limbs were thrown into movements; messages, he concluded, must have been excited which had passed up and down the cord and been reflected to the muscles of the limbs. He touched the posterior roots of a fore and then of a hind limb: the

limbs were thrown into movements; he exposed and touched nerves exposed in the trunk: movements of the limbs and body followed. He touched the skin of the trunk and of the limbs, and with each prick found that the movements evoked by stimulation of the skin were more vigorous than those which followed stimulation of nerves, the nerve roots, or even the cord itself; evidently the skin was the chief end-station for evoking such movements. He noted, in the headless turtle, that the sphincter of the anus retained its normal tonic power and function, but when he destroyed the hinder part of the spinal cord all tone and contraction disappeared from the sphincter. The power or mechanism which regulated the tone or function of a sphincter was clearly resident in the spinal cord. On pricking the headless turtle he could evoke movements in the limbs; it was also clear that in the spinal cord there was resident a mechanism which could time and regulate the contraction of muscles. And lastly and for our present purpose he made a most important observation—when he removed the spinal cord from the headless turtle the limbs became limp, all tone and degree of contraction disappeared from the muscles of the limbs. That passive contracture of muscles which can work such dire deformities in diseased joints was, on Marshall Hall's showing, to be traced to a disordered function of the spinal cord. The spinal cord regulated the balance of the limb muscles and determined the posture of joints.

Marshall Hall was elected a Fellow of the Royal Society in 1832, and on June 20th, 1833, he read to it his paper "On the reflex function of the medulla oblongata and medulla spinalis," in which he demonstrated the existence in these parts of "a principle of action not hitherto distinguished with sufficient precision." We have to remember that in 1833 knowledge of the finer structure of the central nervous system was crude and imperfect; yet he pictured an arc system, and grasped the full bearing of his discovery on the realm of medicine and biology. He had an instinct for signpost facts and critical experiments. He saw that the reflex function of the cord and medulla could be exalted—by opium in the frog and strychnine in the mammal; that the manifestations of tetanus and hydrophobia received a rational explanation for the first time. Asthma and epilepsy he also wished to bring within the scope of his reflex law. The excitomotor or reflex function of the spinal cord he found to be more easily excited in the young than in the old; if a teat touched the lips or a finger pressed the palm of a newly born child, it was grasped by lips or fingers. The anencephalic human fetus he regarded as a purely reflex mechanism. He observed how all the entrances and passages at the front end of the body, all the muscles and operations connected with the entrance of food and breath, were presided over and manipulated by his systems of reflex arcs. The action of the canals and muscles at the hinder end of the body were regulated by a similar system; defaecation, micturition, parturition were reflexly controlled acts. He found he could elicit such acts by stimulating the mucous linings of these canals; tenesmus, stranguary, renal and biliary colic, the localized contractions of the belly wall, and the manifestation of sympathetic pains which accompanied diseases or disorders of the intestinal tract were all brought by him within the scope of his new law. He found that reflexes could be set up by stimulation of the dura mater, plexus, and peritoneum; the muscular disturbances which may attend the eruption of teeth or the presence of worms in the rectum could be explained on his newly discovered system of reflex arcs. His conclusions, which most concern us now, relate to the muscles of the limbs; they, too, were controlled by the action of stimuli speeding along his postulated system of reflex arcs. Stimuli which arose in the moving limb were carried to the spinal cord by "incident" or excitator nerves, and were there "reflected" along the outgoing or motor nerves to the muscles. Each contact of the foot with the ground he supposed to call forth a new series of movements. At first he believed that the "tone" of muscles was also a true reflex manifestation, but later he regarded the tone of muscles as a function of the cord, manifested independently of the arrival of peripheral stimuli.

Marshall Hall as a physician desired to be Nature's servant—a sincere and outspoken servant if not a very humble one. "I am persuaded," he said, "that a knowledge of the healthy body action is the only foundation for

practical medicine and the only remedy for quackery." "A mere practical man is a quack" was one of his aphorisms, yet there never was a man so misconstrued as Marshall Hall was by his contemporaries. The blame is not to be saddled altogether on them, for he had an unconscious art of rousing antagonism, jealousy, and mistrust. We can hardly wonder that John Hilton preferred to think of nerve trunks than of spinal centres as the functional elements which presided over the muscular system of the body. Neither he nor the line of surgeons which followed him perceived that Marshall Hall had given a new basis for the diagnosis of all disordered actions of muscles, and a sure principle in which a rational means of treatment could be based for the recovery of deformed and disabled limbs. Nay, I would go further. The full bearings of Marshall Hall's discoveries, and particularly the significance of the further investigations made by those who have so brilliantly explored the field which he had opened, have not yet been fully utilized by modern orthopaedic surgeons. Marshall Hall made it impossible for us to think any longer in the terms of single muscles, bones, and joints. All of them in the living state are combined into a functional whole by the spinal cord and its system of reflex arcs.

MEDICAL, SURGICAL, OBSTETRICAL.

STERILIZATION OF THE THROAT AFTER DIPHTHERIA AND IN CARRIER CASES.

The detention of diphtheria carriers and of convalescents who continue to harbour the bacillus is irksome to those isolated, and must in the aggregate involve a considerable expenditure of money both in civil and military practice. In the *BRITISH MEDICAL JOURNAL* of March 11th, 1916 (p. 374), Dr. W. S. Thacker reported on the effect of painting the tonsils and nasopharynx with strong solutions of silver nitrate, his work being restricted, I gather, to carriers. He used a 50 per cent. solution, and two applications procured sterility in every case. A 90 per cent. solution was employed for the staff, and one painting then sufficed, the throat being cocaineized beforehand. Used in these strengths the solution has been known to cause severe spasm of the glottis, when it has happened to reach the rima.

At the beginning of August, 1917, we began to use silver nitrate on patients in the Plaistow Hospital positive to the culture test after an acute attack of diphtheria, when otherwise nearly fit to go home. As most of our patients are children, we decided to try the effect of weaker solutions. The first painting was done with a 1 in 8 (12.5 per cent.) solution. Where this did not secure sterility a second painting was done with a 1 in 4 (25 per cent. solution). In four cases this proved insufficient and further painting was needed. These were all children with enlarged tonsils and adenoids. Three of them struggled, so that the solution could not be effectively used. In these cases the throat was thereafter painted under ethyl chloride as a general anaesthetic.

Throat cultures were taken on the third and fifth days after the application. The first culture was positive in three cases only. These were children with large irregular tonsils and masses of adenoids. In fact, it was only in cases of this type that there was any trouble in obtaining sterility, a consequence, no doubt, of difficulty in reaching every depression and irregularity. The cases treated yielded on culture the three types of Klebs-Loeffler bacilli, alone or mixed. Our results do not show that any one of these types is more persistent than the others.

Procedure.

The child was rolled in a blanket so that it could not get its arms free, and laid across the bed with its head in the operator's lap. This position prevented any excess of the solution running down the throat. A strip of cotton-wool wound round long sinus forceps was used for the application with 30 to 40 minims of the solution. The tongue was depressed and the tonsils and posterior pharyngeal wall swabbed somewhat firmly with the silver nitrate. It was found advisable to keep the patient without food for two to three hours beforehand. The only

case in which laryngeal spasm occurred was a girl who had had a meal shortly before the throat was painted. Of the first forty cases treated twenty-eight were sterilized by one application, eight cases by two paintings, and the remaining four cases needed further treatment as described above.

Conclusions.—Of cases with positive cultures after an acute attack of diphtheria 70 per cent. were rendered sterile by one application of a 12.5 solution of silver nitrate. A further 20 per cent. were sterilized by a second painting with a 25 per cent. solution. The remaining 10 per cent. were more resistant but could nevertheless be sterilized with silver nitrate in solutions not stronger than 25 per cent. with a little patience.

On the whole Dr. Thacker's method of sterilization marks a greatly needed advance on the preventive side, and it is to be hoped that its adoption in other contagious diseases than diphtheria will prove useful. In practice its efficacy plainly depends on the thoroughness with which the silver nitrate solution is applied over the entire surface of the mucous membrane.

Senior Resident Medical Officer,
Plaistow Hospital.

VINCENT'S ANGINA.

HAVING recently taken swabs from numerous cases of Vincent's angina, and having read various short articles on the prevalence of the condition both amongst our overseas troops and amongst the home service units, we are surprised to find no mention of the condition of the gums in this infection. In several cases the throat has cleared up in eight to ten days, while the organisms have easily been demonstrable in pus around the teeth; and, vice versa, in more than one case the patient has come up for a sore throat (? Vincent's angina), and we have found the organism in periodontal pus in great quantity whenever a swab from the tonsil has been indeterminate.

There seems to be no doubt that it is of the highest importance to look for pyorrhoea or other dental trouble in every case of sore throat, as a diagnosis may often be made in cases where nothing is obtained in direct tonsillar smears.

Moreover, no patient who has been under treatment for Vincent's angina should be discharged until it is shown that swabs from around the teeth are negative. We have swabbed several cases of pyorrhoea and several normal throats, and although fusiform bacilli and spirillar forms are occasionally seen, we are satisfied that Vincent's angina can be readily diagnosed from direct smears of the gums and throat, and that no other condition ordinarily met with presents the same microscopic picture.

WOUND INFECTION.

EVEN at the risk of the accusation of repetition I consider it my duty, in present circumstances, to draw further attention to the excellent results which may be obtained in desperate compound comminuted fractures and other grave septic wounds by the prompt administration of ether, application of a tourniquet, deliberate exposure, and obliteration of pockets and sinuses by large incisions, complete removal of foreign bodies (including dequided infected fragments of bone), thorough tunnel gravity drainage, efficient haemostasis, frequent irrigation with hot peroxide lotion (60 to 120 c.cm. to litre), followed immediately by hot carbolic lotion (15 c.cm. to litre), hot mercury perchloride (1 in 2,000) fomentations (wrung dry before application), and absolute rest on a suitable splint until the wound is healed, with extension when necessary. To this should be added, whenever possible, permanent outdoor treatment, which is infinitely preferable to any indoor "primrose sunlight" illusion, and a liberal allowance of wine, stout, or beer with meals.

As far as my personal experience is concerned I have yet to find the equal of the above combination of surgical principles with what, in my opinion, are the best of all

antiseptics, so long as the latter are not used in a strength to destroy friend and foe alike; and their action is considerably enhanced by heat (fomentation) to the part and complete rest to the limb.

Senior Medical Officer, British
Hospital, Buenos Aires.

DISLOCATION OF BOTH HIPs WITHOUT FRACTURE OF PELVIS.

J. G., a miner, aged 42, when in a stooping position was knocked down by a fall of stone. When examined it was found that his left leg was flexed, adducted, and internally rotated, and the right leg flexed, abducted, and externally rotated. Both dislocations were easily reduced under an anaesthetic. Stimson in his book says that thirty cases have been reported. Usually the dislocation is not the same on both sides.

ELECTRO-PHYSIOLOGICAL PHENOMENA.

A MEETING of the Electro-Therapeutical Section of the Royal Society of Medicine was held on December 21st, 1917, when Mr. A. E. BAINES read a paper on *The Interpretation of Certain Electro-Physiological Phenomena*. Replying to Professor Bayliss's criticism¹ of a book partly written by him, he explained that certain statements said to embrace the chief errors underlying the thesis were made by Dr. Bowman of Manchester and not by him. Other essential points in the criticism were that the currents led off from various points of the body by metallic electrodes were due to the inequality of the electrodes and to difference in the activity of the skin glands; that nerve leaks were merely places at which the skin was moist; and that the di-electric bearing his name did not appear to be different from some kinds of medicinal paraffin.

In refutation Mr. Baines stated that in taking a hand-to-hand galvanometric deflection the sign of current was always changed when the hands were crossed, showing that difference of polarity was in the hands and not in the electrode; that unless both hands were used the contact of skin and metal did not exhibit electrical action, and that as the thumbs were electrically, as well as anatomically, in opposition to the fingers of the same hand no current would pass if the electrodes were placed between the first and second and third and fourth fingers of the same hand, but that a current passed when the thumb made contact and established a potential difference by reason of its higher and opposite electrification. He also referred to the experiments of Dr. C. N. Longridge, published in the *BRITISH MEDICAL JOURNAL* of May 20th, 1916, and instanced the fact that whereas in neurasthenia, where the hands were moist and the deflection small and of uncertain sign, there was always a large and rapid excursion of the light from a dry hot skin in local pyrexia. Upon the question of paraffin, he claimed that the use of a rock oil was clearly indicated by an electro-pathological study of local pyrexia. Clerk-Maxwell and Sir Oliver Lodge had told him, he said, that light is an electro-magnetic disturbance of the ether and optics a branch of electricity. Progressing from the red to the violet end of the spectrum, there must be a rapid increase in the potential of light, and a discharge of electricity of ever-increasing intensity. In the early days of experimentation with a mineral oil of correct viscosity there had been many failures, and he had found that when exposed to direct sunlight or ultra-violet rays there was a distinct falling off in its therapeutic value. His process was designed to remedy that defect, and since the oil had been standardized there had been no failures that could not be ascribed to faulty diagnosis. If objection were taken to the process on the ground that it was secret, he said that the paraffin prescribed by the medical profession for constipation had always been refined by secret processes.

Rebiefus.

ON WRITING WITH THE LEFT HAND.

THE author of this treatise aims at providing a practical method of left-hand writing for the use of the mutilated, the subjects of cramp or paralysis, and the left-handed. The work is of interest at this moment when so many men, as a result of the war, have lost the right hand. Professor D'Urso enters at some length upon a discussion of the rationale of the process of handwriting, especially as regards the direction of the writing with reference to the position of the body and of the pen. He gives some ingenious diagrams, which he maintains are based upon sound physiological and geometrical grounds. A scheme for the right hand having been constructed, he proceeds to show what must of necessity be the scheme for left-hand writing, if the one limb be regarded as the counterpart of the other. He shows also that the direction of the writing with reference to the axis of the body is varied according to the obliquity of the letters. The practical outcome of the discourse is as follows.

In learning to write with the left hand the pupil should commence by writing the various letters on a blackboard with chalk, standing. He should commence with letters 8 cm. in height, then form letters of 4 cm. and finally those of 2 cm. The larger letters will be written from the shoulder and elbow, the wrist and fingers being almost immobile. He should then proceed to write on paper, the paper being placed on a horizontal table. He should commence with letters 4 mm. in height, and then follow with letters of 2 mm. At first a pencil should be used, and, after some proficiency is obtained, a pen. The exercises are no other than those that are to be found in any English child's copybook. The "hand" adopted is *la scrittura corsiva*, or running hand, the letters of which are inclined at an angle of 45 degrees. Little attempt should be made to distinguish the heavy down stroke from the lighter up stroke. The paper should be smooth and ruled in faint lines. At first the pupil may trace over already pencilled letters. The pupil should not go over his writing twice nor retouch letters after they are made. The paper should be fixed in position by means of a paper weight. The light should fall from the right-hand side. The nib used must be fine and flexible, and with a median point. The pen-holder should be slender and light. The writing should be as light as possible. It is a common error to grip the pen too firmly, and to press too heavily on the paper. The pen should be lifted from the paper as seldom as possible. The writing must never be hurried, nor persisted in for longer than one hour at a time.

The pen is held in the left hand precisely as it is held in the right—that is, between the index finger and the thumb. The pen should rest upon the base of the index and be in a line with the forearm. It will be noticed that while the finer movements of the pen are controlled in the right hand by the index finger, in the left they are rather influenced by the thumb.

The most important feature in the author's method is position. The writer must sit square to the table, bolt upright, with his chest to the table's edge. He must resist the inevitable tendency to lean to the right. The whole of the forearm should rest on the table, the elbow being at the edge of the table. The paper should be so turned that the lines to be written on are vertical, as viewed by the writer, and not horizontal; that is to say, the lines should be at right angles to the edge of the table; the top of the page will therefore be on the right-hand side of the pupil and the bottom on his left. The left-handed man, in fact, should write vertically from above downwards, and not horizontally from left to right, as is the practice when the right hand is used. The pen is held at right angles to the lines. The paper, it is needless to say, is flat on the table, but the writing is at right angles to the edge of the table and not parallel with it. Any one who attempts left-hand writing will experience at once the convenience of writing vertically.

FREDERICK TREVES.

ACIDOSIS.

The conception of acidosis, which may be defined as the depletion of the blood and other tissues of the body in fixed bases, actually dates from 1850, but has only become generally recognized by medical practitioners comparatively recently and almost exclusively in one manifestation—namely, carbohydrate acidosis as seen in diabetes.² The blood plasma is kept uniformly alkaline by the intake of fixed bases in the food, the elimination of CO₂ by the lungs and of acid by the kidneys, and by the neutralization of acids in the body by ammonia. In well-marked acidosis the carbonates of the blood become depleted, CO₂ accumulates in the tissues, and although oxygen is carried by the arterial blood the tissues are unable to make use of it, there is no cyanosis, the venous blood is arterial in colour, and, as death occurs before there is any significant change in the reaction of the blood, acidæmia is an unfortunate term. Acetone bodies in the urine appear in carbohydrate acidosis only.

The recognition of other forms of acidosis is an important advance. They occur in renal disease, in advanced hepatic cirrhosis, in cholera, and in food poisoning in children. Acidosis does not occur in parenchymatous nephritis or in the early stages of the chronic interstitial or the arterio-sclerotic forms, but it appears in the later course of granular kidney, becoming prominent in uræmia, and is present in the uræmia of acute nephritis. In the renal form of acidosis there are no abnormal acids or excess of ammonia in the urine, but the amount of inorganic phosphates in the blood is increased and convulsions appear to be connected with the deficiency of calcium in the blood. Dr. SELLARDS has specially studied the acidosis of cholera and points out that it is intermediate between the carbohydrate and renal forms, as there is an increase of ammonia but no acetone bodies in the urine. The injection of massive doses of sodium bicarbonate during the collapse of cholera prevents the subsequent appearance of uræmia. It is of interest to note that there is no evidence that the hypothetical opposite condition of "alkalosis" occurs spontaneously in man or in animals, though after parathyroidectomy "alkalosis" appears before the onset of tetany, and benefit results from the administration of acids. This monograph conveys a broad view of acidosis, and in a very compact form contains a great deal of information which will be new to most medical practitioners.

ELECTRO DIAGNOSIS IN WAR.

In the greatly extended field of neurology due to the war electrical testing by its precise, almost mathematically exact, results greatly adds to the accuracy of diagnosis and prognosis; thus, in a doubtful case the partial reaction of degeneration points to compression or some other curable lesion of the nerve, whereas the complete reaction of degeneration shows that the continuity of the nerve has been severed; again, the report of the electrical reactions may decide whether or not there is an organic lesion underlying functional manifestations. The editors of the Collection Horizon have therefore been well advised to include in it a volume on electro-diagnosis,³ giving an up-to-date account of the applications, results, and limitations of the subject. The authors, Professor ZIMMERN and M. PÉROL, after a description of methods, illustrated by forty-four figures, devote a chapter to the abnormal reactions among which that of degeneration naturally receives the fullest attention. The diagnosis of motor paralysis and sensory disturbances is then discussed; in muscular atrophy secondary to arthritis the electrical reactions are exclusively in the direction of quantitative modifications of irritability, and the reaction of degeneration never occurs; so in atrophy about the shoulder-joint after injury the reaction of degeneration points to neuritis or compression of the circumflex nerve, or to radiculitis. The altered reactions in ischaemic paralysis, though sometimes referred to anaemia, are, the authors consider, more logically explained as due to neuritic and muscular changes, or to

compression of the nerve filaments by fibrous tissue. An interesting account of voltaic vertigo as a vestibular test is accompanied by explanatory figures. Like the other volumes of this series, this can be recommended for its practical utility.

GUNSHOT FRACTURES OF THE ORBIT.

M. FÉLIX LAGRANGE has contributed a volume on gunshot fractures of the orbit⁴ to the Collection Horizon. After a comprehensive historical survey of the subject and a description of the anatomy and functions of the orbit, he analyses the 609 cases on which his monograph is founded. Sight was destroyed in 34.5 per cent. of his cases, due to such lesions as detached retina, chorio-retinitis, atrophy of the optic nerve, haemorrhage into the vitreous, retrobulbar neuritis, cataract, or dislocation of the lens. He found that 18 per cent. of the cases were complicated with lesions of the maxillary antrum and 5 per cent. with injury of the frontal sinus. He calls attention to the fact that these lesions of the eye may occur when neither the projectile nor detached bony fragments have touched the globe. Partial rupture of the sclera, which, according to the theory of the "equator of depression," might be expected, does not occur. If the eyeball is struck by a large fragment of metal it is crushed and entirely destroyed; where the fragment is small it may penetrate the globe. Scleral rupture in the intercalary region rarely or never occurs. As to the treatment of sympathetic ophthalmia, the author is on the side of those who favour enucleation, but makes, of course, certain exceptions. M. Lagrange lays down the following principles in the treatment of gunshot wounds of the orbital region: (1) The eyelids must be replaced in their proper position and as far as possible in their normal form. (2) The conjunctival cul-de-sacs must be restored so that they may be capable of holding the artificial eye. (3) The external form of the orbit must be re-established as nearly as possible by filling up the osseous gaps. For this purpose metallic plates, or preferably fatty or cartilaginous grafts, are employed. The grafts are taken from the patient, either from the buttock when adipose tissue only is required, or from the costal cartilage when cartilage is wanted in addition. The treatise deals in a comprehensive way with a somewhat limited branch of war surgery, which perhaps has not received all the attention it deserves.

THE GENTLE ART OF GROWING OLD.

The later years of life are too often beset with major or minor troubles of which youth knows nothing, but with all its drawbacks and deprivations, old folks as a rule desire to cling to life so long as they can enjoy it.

How to make the most of one's life and at the same time to prolong it as far as possible should be the study of all persons of both sexes. To point out the road by which a healthy old age may be reached has been the task of many writers from Cicero downwards. A small work from the pen of Dr. BODLEY SCOTT⁵ has recently appeared in which the subject is discussed in terms at once graceful, sympathetic, and informative. The writer, who has already given evidence in a previous work of careful study of the conditions that are favourable to longevity, is able to pass most of them in review from the standpoint of personal experience.

The idea that life must pursue a downhill course after the period of maturity is passed, and that disease and decay must needs follow, is altogether repudiated. Although growth may have ceased, the fruit of experience is ripening, and can be maintained in good condition for the benefit of others, if only the physical organism can be protected from those risks of injury or degeneration to which all persons of advanced age are liable. In the earlier chapters the mental, rather than the physical, conditions are discussed, over which the individual has more or less control. A large proportion of the errors of conduct which lead to an unlovable old age are easily to be avoided, if certain habits are recognized and corrected in time.

The question of food enters largely into the scheme of physical well-being, and the possession of sound digestive and assimilative power is a prime factor in the attainment of a healthy old age. Errors of quantity as well as of quality of food are apt to be cumulative in their effects, and only manifest themselves when irreparable mischief has been done. In spite of such errors in early life there may be good health at maturity, but as years advance more rational methods have to be adopted. By comparison with the life periods of certain animals, the writer concludes that human life should be prolonged to ninety years. In the later chapters the causes of premature senility are closely examined, especially with reference to cardiac and vascular degeneration.

We can cordially commend this work to readers of advancing years, whether medical or lay. To the former it presents an old subject in a new way, and to the latter will convey some very wholesome material for thought.

THE CAUSATION OF SEX IN MAN.

SOME thirty years ago Dr. E. RUMLEY DAWSON began to study the vexed question of the causation of sex in man. At the end of the year 1900 he propounded an original and simple theory of the subject. He holds that the sex of the child depends solely upon which ovary supplies the ovum fertilized. If the ovum comes from the right ovary, the child is a boy; if from the left, a girl. The father has no influence in determining the sex of the future child, nor have any of the countless old and new recipes for the production of a child of a specified sex. This theory has all the attraction of extreme simplicity, and in the second edition of his book⁶ on the subject Dr. Dawson has collected a great deal of evidence to prove its correctness, both from his own experience and from gynaecological literature. He also devotes a chapter to rebutting the evidence brought forward by various writers to disprove his theory.

Another chapter is given to a second theory of the author's, designed to make possible the prediction of the sex of coming children in multiparae. The second theory is this, that the ovaries ovulate alternately, and it is supported again by a considerable body of evidence. Dr. Dawson claims 97 per cent. of successes in his predictions of the sex of unborn children. Naturally there are limitations in the making of such forecasts, and these are duly pointed out by the author. As a corollary the production of children of either sex as desired should, again within limits, be possible in the case of multiparae; again, Dr. Dawson claims that he has been successful here in many instances.

It is clear that Dr. Dawson's theories are ambitious, for they offer solutions of problems attacked by medical men and biologists again and again, at any rate since the time of Hippocrates. But are his solutions correct? This question is merely one of fact, and the answer will depend only upon the evidence afforded by the collection of observations. Thus valuable evidence for or against his view that the right ovary produces male ova and the left female could be collected at Caesarean operations; the sex of the child could be compared with the site of the ovarian corpus luteum. Similar evidence could be collected in the *post-mortem* room. Dr. Dawson's book is well written and its subject matter is clearly arranged. Its topic is one of such general interest that it is highly desirable that Dr. Dawson's theories should be submitted to the test of clinical observation, as has been partially indicated above. Their truth or error can be proved in no other way.

LUCIANI'S "PHYSIOLOGY."

THE fourth instalment of the English version of Professor LUCIANI'S *Human Physiology*⁷ is devoted to the sense organs, and includes a full account of the sensibility of the viscera, with adequate recognition of the advances made by Head and other British workers. In the concluding chapter, on the psycho-physical phenomena of consciousness and sleep, a comparison is drawn between

the conscious and unconscious mental processes which are not sharply separated but merge into each other in the nascent or twilight consciousness. The late F. W. Myers's opinion that "an inspiration of genius is in truth a subliminal uprush," or the penetration of the psychical diaphragm between consciousness and subconsciousness by the workings of the subconscious mind, is supported by an interesting account of the mental process attending the discovery of the Fuchsian functions by Henri Poincaré, the great mathematician, whose death French science had recently to lament. As has been said in previous reviews, Luciani's book has the lucidity, literary charm, and philosophical outlook that characterized Sir Michael Foster's textbook in the eighties and nineties. The English is so good that the reader is never reminded that it is a translation, and so perhaps is inclined to forget his debt to Miss Welby and Dr. Gordon Holmes; the general get-up is worthy of the traditions of the publishers.

NOTES ON BOOKS.

MR. ARNOLD J. TOYNBEE, one-time Fellow of Balliol, has prepared a volume entitled *The German Terror in France*,⁸ which is a continuation of his volume with a similar title on Belgium. Both books are compilations from official documents illustrated by photographs and excellent sketch maps. In his new volume the facts are classified under the four regions overrun by the Germans, and arranged chronologically. The book is only intended to be a general summary and to serve as a guide to the official documents in the Bryce report and in the reports of the French, Belgian, and German Governments. The book is, of course, very much condensed because, as Mr. Toynbee says, for those who read the tales there comes a point where imagination rebels or is blurred by mere repetition. Beyond the parrot cry "It is war," the Germans have made no reply except to say that their object was to confer the benefits of their civilization on the French and Belgians. They do not call it civilization, but *Kultur*, which is perhaps as well, for the latter word means no more than the way a nation understands the organization of a community. The German bases his *Kultur* on war, and considers rape, murder, mutilation, and arson legitimate methods of warfare and appropriate means of convincing other nations of his intellectual superiority. The stage of mentality reached by his subjects may be judged by the Kaiser's Christmas assurance to them that 1917 has proved that they have "in the Lord of Creation above an unconditional and avowed ally."

The Annals of Medical History, a beautifully got up periodical, recalling the *Burlington or Connoisseur* in its typography and illustrations, deserves a generous welcome from all, and they are an increasing band, interested in the history of medicine. The editor, Dr. F. R. Packard, and the publisher, Paul B. Hoeber, who were recently associated in the artistic reprint of MacMichael's *Gold-headed Cane*, are supported by twelve associate editors, of whom one, Sir William Osler, is on this side of the Atlantic. Appearing quarterly, the *Annals* contain original articles, reviews, notes and queries, and is free from any advertisements; these attractions, and the knowledge that it is the only periodical in English exclusively devoted to medical historical literature, should ensure it a large subscription list at six dollars a year. The first number, dated April, 1917, but reaching us several months later, opens with a scholarly article on the scientific position of Girolamo Fracastoro by Dr. and Mrs. C. Singer of Oxford. This is followed by Dr. F. H. Garrison on the Greek cult of the dead and the Chthonian deities in ancient medicine. In a sympathetic account of Voltaire's relation to medicine Dr. Pearce Bailey of New York does honour to a great and far-sighted reformer to whom medicine owes no trivial debt. Dr. C. W. Barr gives an interesting study of Burke and Hare and the psychology of murder, with Forbes's portrait of Robert Knox reproduced from the *Students' Magazine*. Dr. C. D. Spivak writes on Hebrew prayers for the sick, and quotes the briefest prayer on record, by Moses, consisting in the original of five short words. "Laryngology and otology in colonial times" is the title of an article by Dr. S. A. Friedberg, based on a manuscript of the eighteenth century. Then come the editorial, a short but interesting note on the legend of the mandragora, and lastly, reviews of books. The subscription price for the *Annals*, which appear

⁶ *The Causation of Sex in Man*. By E. Rumley Dawson, L.R.C.P., M.R.C.S. Second edition. London: H. K. Lewis. 1917. (Demy 8vo, pp. xiv + 226; 22 figures. 7s. 6d. net.)

⁷ *Human Physiology*. By Professor Luigi Luciani. Translated by Frances A. Welby. Edited by Gordon Holmes, M.D. Vol. iv: The Sense Organs. London: Macmillan and Co. 1917. (Pp. 519; 216 figures. 21s.)

⁸ *The German Terror in France*. By Arnold J. Toynbee. London: Hodder and Stoughton. 1917. (Demy 8vo, pp. xv + 212; 52 illustrations, 6 maps. 1s. net.)

quarterly in April, July, October, and December, is 6 dollars yearly and 2 dollars for single numbers, and should be sent to the publisher, Paul B. Hoeber, 67-69, East 59th Street, New York, N.Y., U.S.A.

The *Medical Directory*⁹ for 1918 makes its appearance punctually and contains the matter which has rendered it for very many years so useful to the medical profession. It is, in fact, an indispensable work of reference for all concerned with medical administration, whether military or civil, and we could wish that a copy was to be found in the office of the principal medical officer of all the military forces at home and abroad. The number of names it contains shows an increase of 152 as compared with the issue for 1917, and of 459 since 1915. As compared with ten years ago the increase is 3,126. The number of names in the London part of the *Directory* is exactly the same as in 1917; in the rest of England there is a decline of 96, and in Wales an increase of 2. In Scotland there is an increase of 148 and in Ireland of 129; abroad there is an increase of 31. We give these figures for what they are worth, but they are open to an obvious fallacy, as is indicated by the fact that a decrease of 62 is shown in the number of names in the list of the services. The figures afford no sure indication of the number of practitioners actually in practice at the addresses given, for so many withdrawn for military service still appear, as is proper, under their home address.

⁹ The *Medical Directory*, 1918. Seventy-fourth annual issue. London: J. and A. Churchill. (Roy. 8vo, pp. 1958. 15s. 6d. at home; 18s. 6d. abroad.)

THE EFFECT OF LIQUOR CONTROL UPON ALCOHOLISM IN WOMEN.

In the *JOURNAL* of May 19th, 1917, page 651, we gave a summary of an address by Lord D'Abernon on public health and the control of the liquor traffic. He has now supplemented this by a further address given to the Royal Institute of Public Health, on December 19th, dealing with the effect of the regulation of the liquor traffic on alcoholism in women. The importance of this subject may be judged from the fact that the number of women now in industrial life and in non-sheltered occupations common to men, exceeds by nearly a million and a half the number so employed before the war. Moreover, this increase in the number of women workers has been associated with a large rise in the average wage of female labour, so that the annual spending power of women is now estimated to exceed by something like two hundred million pounds that which they had before the war, without taking into account the allowances made to the wives and dependants of soldiers and sailors. This profound change of circumstances has led, as might be expected, to a larger use of public-houses on the part of women. But the anticipation based on previous experience that alcoholic excess would be greatly encouraged among women has been falsified. While the number of women exposed to alcoholic temptation and possessing the means to gratify the inclination has enormously increased, statistical and other evidence indicates that insobriety among women, both in public and in the home, has since 1914 decreased to a level far below anything recorded during the last fifty years. While the number of women employed increased during the first three years of the war by more than 40 per cent., female convictions for drunkenness decreased by 73 per cent.

That the decline in insobriety is not confined to public drunkenness is shown by a corresponding decline in sickness and mortality from alcoholism, and from other conditions generally recognized as due to excessive drinking. Comparative statistics for delirium tremens are only available for a few of the larger towns, but in Liverpool, for instance, the number of female cases of this disease have fallen by more than 80 per cent. below the figure for 1914. The tendency of the movement as a whole is clearly visible in the figures of mortality from alcoholism and alcoholic diseases in England and Wales recently given by the Registrar-General. These show a decline of more than 50 per cent. since 1914. It would thus appear that the reduction in the hours for the sale of alcohol in licensed houses has not driven drink into the home, and this view is supported by the recent decline in suicide among women, and in the cases of suffocation of infants under one year

of age, as well as in female mortality in London from cirrhosis of the liver.

Lord D'Abernon next discussed the influence of the various restrictive and other measures affecting the liquor traffic upon the recent decline in excessive drinking. The restrictive measures of the Liquor Control Board have now been in force for over two years, and their effect was fully discussed by Lord D'Abernon in his previous address. As regards constructive measures to increase opportunities for non-alcoholic refreshment, he speaks in terms of warm appreciation of the good work done by the Canteens Committee of the Board in supplying canteens and messrooms in national factories and controlled establishments and in the neighbourhood of docks; and he is convinced that the system will before long be generally adopted throughout the industry of the country.

Turning to the restrictions of the Food Controller upon the output and release from bond of alcoholic liquors, he notes that these are clearly of a temporary kind intended to meet new food conditions due to the war. Their precise effect upon sobriety is difficult to measure; in so far as they have driven up prices, their influence may be considered beneficial; they also encourage retailers to dilute spirits to the new level, and promote the brewing of weaker beers. On the other hand, the drastic cutting down of supplies causes uncertainty as to the likelihood of obtaining liquor with periods of "rush" drinking; and it might be added that "whisky queues," and the like, are, to say the least, an unedifying waste of public time. Viewed solely from the point of view of temperance and efficiency, Lord D'Abernon regards these alternations of plethora and famine as clearly undesirable, and a considerable set-off to the good effect of higher prices. The emergency restrictions upon output are thus on quite a different footing from the restrictive and constructive measures of the Liquor Control Board, and Lord D'Abernon makes out a strong case for maintaining the latter after the war, being convinced that restriction and regulation on reasonable lines are not only needed on national grounds, but are beneficial to trade interests. He concluded by arguing that the influences checking public drunkenness must also have done much to raise industrial efficiency by reducing the extent and intensity of chronic alcoholic poisoning in its less pronounced forms and earlier phases. In view of this, and of the marked improvement in the care of children and of the home, attributed by medical officers of health and others to liquor restrictions, he cannot believe that any responsible body of opinion would wish to sacrifice the ground gained and relapse into pre-war conditions.

PUBLIC HEALTH OF ENGLAND AND WALES IN 1916.

The supplement to the forty-sixth annual report of the Local Government Board, containing the report of the medical officer for 1916-17, appeared recently. Sir Arthur Newsholme begins by pointing out that a review of the national health during the year has again been rendered exceptionally difficult by the disturbance of population due to war and to the vast new industries created during the war. For the same reasons the medical officers of health have found great difficulty in accurately estimating populations when recording birth and death rates. With the single exception of measles, the record of ordinary infectious diseases has remained favourable. In this respect the first three years of the war gives cause for satisfaction. During 1916 measles and German measles were for the first time notifiable, and throughout England and Wales some 348,000 cases were notified, giving a rate of 1 per cent. of the population.

The report indicates a number of important health services which have been prejudiced by the war; against this there is to be set the much increased attention paid to the means of improving the health of mothers and young children. Certain local authorities still remain inert and unteachable, but generally speaking there was during 1916 a great growth of work on behalf of maternity and infant welfare. The need for redoubled effort in these directions is emphasized by the diminished natural increase of population during the two years. In 1914 there were 362,354 more births than deaths in England and

Wales; in 1915 this excess of births over deaths was only 252,201; while in 1916 the excess was 277,227. These figures reveal the importance of saving child life and of improving the health of all survivors, and in this connexion Sir Arthur Newsholme expresses the opinion that there is no insuperable difficulty in reducing the total deaths in childhood to one-half their present number. It is encouraging to note here that during 1916 the rate of infant mortality was the lowest on record.

The Claims of the Army.

The annual report for the previous year made reference to the demands of the army for medical practitioners, and, as is well known, these have become still more urgent, with a corresponding increase in the work of inquiring into each case in which the release of a public health officer for military service is concerned. A large number of both whole-time and part-time medical officers of health for England and Wales have now left their civil work for service with the army. Their places have in a number of cases been filled by women. Two medical women are now acting as county medical officers of health, while many more hold official appointments as tuberculosis officers and assistant tuberculosis officers. But the depletion of the public health services has become serious, and unless considerable readjustments are made, more medical officers cannot be spared consistently with the public safety. While more than 500 public health officers have joined the forces, the subordinate staffs of sanitary inspectors have also been greatly depleted, with the result that many untrained men and women are carrying out the duties formerly in the charge of trained men. It is scarcely surprising to learn that under such conditions outbreaks of infectious diseases have here and there not been promptly controlled. Moreover, especially in regard to small-pox, enhanced risks have had to be taken owing to the inexperience of the local officers, and much of the time of those medical inspectors of the Board who are not on military duty is taken up in emergency work arising therefrom. This section of the report closes with a tribute to the medical officers of health and sanitary inspectors remaining on civil duty, who have not only done admirable work in their own districts but have assisted less experienced colleagues in other districts.

Enteric Fever.

The prevalence of enteric fever, says the report, is, perhaps, the best single gauge of the sanitary condition of the community; and it is satisfactory, therefore, to note that following on the steady decline of this disease during the last thirty years, there has been during the last two years a striking fall in the number of cases. In 1911 there were 13,852 cases notified in England and Wales; the number has steadily fallen year by year to 5,564 in 1916. It appears that some areas are still remiss in notifying cases of enteric fever, with consequent risk to the community and confusion of statistics. The more considerable local outbreaks were investigated by the Board's medical inspectors, and some of their inquiries are briefly described in the report. As in previous years of the war the medical department of the Board kept in touch with the Army Medical Department as to the precautions to be taken upon the discharge of military convalescents from typhoid and paratyphoid fever. Thorough and systematic arrangements have been made for the transfer of such convalescents to enteric dépôts, where bacteriological examinations for the discovery of carrier cases are made before each patient is discharged. Upon his discharge from the dépôt notification is sent to the medical officer of health for the locality where the man intends to spend his furlough. Similar arrangements as regards dysentery have also been in force for some time, and nothing but good can come of such co-operation.

Polio-myelitis.

There was a very severe outbreak of this disease in New York City during 1916, with 8,900 cases and 2,400 deaths, but nothing of the sort, fortunately, occurred in this country. The possibility of such outbreaks, however, justifies the close watch kept on the prevalence of this disease and the collection of all the facts of individual cases with a view to the accumulation and analysis of

epidemiological evidence. Continued study of the conditions under which this disease occurs is imperatively needed: "Not only does its fatality amount to about 14 per cent., the greater number of the victims being young children, but one-half of the survivors remain permanently crippled." In view of these facts, Sir Arthur Newsholme does well to remind medical officers of health of the important aid they can give in enabling patients who have suffered from polio-myelitis to become efficient members of society. Notified cases should be periodically visited and parents should be impressed with the importance of securing suitable treatment promptly and continuously, so as to minimize the deformities otherwise likely to occur.

Tuberculosis.

The longest section of the report is devoted to the subject of tuberculosis. The total deaths from this disease during the past six years are set out in a table. Comparing 1913—the last complete year before the war—with subsequent years, deaths from pulmonary tuberculosis were 1,582 more in 1914, 4,621 in 1915, and 4,490 more in 1916. This increased mortality from pulmonary tuberculosis was shared by both sexes, and was not reflected by a corresponding increase of deaths from other forms of tuberculosis. The assumption that it was due to the altered conditions of life during war time must be considered in relation to collateral experience of other diseases, notably influenza, pneumonia, and bronchitis. The figures for 1915 and 1916 show that the increased death-rate from pulmonary tuberculosis was associated with a still greater mortality from influenza, just as was the case in the years 1890–1892, and again in 1899–1900. The year 1915 was notable also for the high death-rate from pneumonia and bronchitis; but in 1916 the deaths from pneumonia no longer occurred in excessive numbers, whilst the excess in deaths from influenza and from bronchitis continued on a smaller scale than in 1915. The only safe inferences from these figures seem to be that influenza is a very dangerous complication of pulmonary tuberculosis, and that the war conditions of the past two years have had an important share in the excessive mortality from all four diseases. Men in the army and men and women in industrial employment have been exposed to conditions leading to the spread of tuberculosis and to the calling into activity of latent disease. The experience of the Continental countries engaged in the war seems to be the same. In all of them, so far as official records are available, tuberculosis appears to have been more rife and more fatal than before the war. In our own country, at least, this unfavourable record would no doubt have been worse but for organized efforts to secure improved conditions of work and housing for munition workers.

In view of this association of war conditions with a notable increase of pulmonary tuberculosis Sir Arthur Newsholme gives an instructive summary of the special action taken in recent years for the control of tuberculosis. Between January 1st, 1909 (when Poor Law cases of pulmonary tuberculosis became compulsorily notifiable), and the outbreak of war, a series of important steps were taken in the direction of the administrative control of tuberculosis. These efforts were meeting with increasing success until the war rudely intervened, and not only put a stop to further developments of organized antituberculosis work, but seriously crippled the efficiency of existing measures. The linking up of the different agencies required to secure the full benefit of the schemes has also been seriously retarded by the war.

The difficulties and defects of the tuberculosis arrangements hitherto made are set out by Sir Arthur Newsholme with a view to further action directed to their removal. In normal times a large proportion of consumptives refrain from applying for treatment until the disease is fully established and they are incapacitated for work. In the three years of the present war temptations to neglect symptoms pointing to consumption have increased, as have temptations to conceal the fact of the existence of consumption. With regard to the private practitioner, it is pointed out that early recognition and treatment depend upon his skill, upon his having adequate time for the examination of each patient, and upon his willingness to refer doubtful cases for consultation with the tuberculosis officer. In the circumstances of war, when nearly every doctor remaining in civil practice is overworked, these conditions cannot at

present be fulfilled. The report is especially insistent on the need for greater co-operation between the family doctor, the tuberculosis officer, and the medical officer of health. If this took place generally a much higher proportion of cases would be recognized at the earlier stage when no sputum is available, and the tuberculous character of many cases of so-called chronic bronchitis would be recognized. The question is discussed at some length why sanatorium treatment as hitherto developed has fallen short of expectations, and the opinion is expressed that the best results are only to be got when the form of treatment in every case is determined solely by the medical needs of the patient. The hygienic conditions of the patient's home should influence this decision, but if regard is had to any other considerations institutional treatment must continue to give relatively unsatisfactory results. This section of the report ends with the maxim that housing and institutional treatment for tuberculosis are to be regarded not as alternatives, but as necessary complements to one another, each calling for increased expenditure.

Venereal Diseases.

During the close of the period under review much of the time of officers of the medical department was given to work in connexion with the setting up by local authorities of schemes for the treatment of venereal diseases. These schemes owed their origin to the regulations issued by the Board in July, 1916, which were followed by conferences between medical inspectors of the Board and local officials. By the end of last March eighty-six out of 145 councils had submitted schemes, of which forty-five were approved. Valuable help was given by the National Council for Combating Venereal Diseases in dealing with the curious objections raised by squeamish hospital boards, and in arousing local interest in local schemes. The Army Council has also assisted in certain districts by allowing R.A.M.C. officers with special experience of venereal diseases to be appointed for this work. The evidence given before the Royal Commission and the experience of the army have led medical officers of treatment centres to use salvarsan substitutes very largely in the treatment of syphilis, especially in its early stages. This course is considered most desirable by the Board, but medical officers of centres are in no way limited as to the choice of remedies for each particular case. Where specially trained experts are not available the Board discourages arrangements for making the Wassermann test in the laboratories of local authorities. It has also decided that pathologists under venereal disease schemes are not to be approved unless they are medical men, and therefore in a position to apply the knowledge obtained by medical training to problems arising in connexion with specimens taken from patients suffering from or suspected of venereal disease. With regard to gonorrhoea, it is noted that the treatment of this disease even under the best conditions does not compare in efficacy and in the rapid reduction of infectiousness with the treatment of syphilis by arseno-benzol preparations. Prompt and early treatment of gonorrhoea is of primary importance, and arrangements have been made with the Army Council for Colonel Harrison to provide, for publication by the Board, in a form available for civilian practitioners, the valuable experience obtained by army doctors in the control of this disease.

Miscellaneous.

The concluding sections of the report deal with maternity and child welfare work, in which there has been much activity under pressure by the Board; with scientific investigations conducted under the auspices of the Board; and with the personnel of the medical staff, more particularly in respect of war services. On the outbreak of war all the medical inspectors of the Board at once placed their services at the disposal of the president for service in any capacity. Among those who were chosen for commissions was Dr. J. Morgan Rees, who was killed in France in October, 1916, while serving in the R.A.M.C. The appendices to the report include a summary of information on cases of poliomyelitis by Dr. R. J. Reece; Dr. A. W. J. MacFadden's valuable report on the work of inspectors of food; Dr. Eastwood's report on the work of the Board's pathological laboratory; and Dr. F. R. Blaxall's report from the Government lymph establishment.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on Tuesday, November 13th, 1917, thirty-five cases were considered, and £330 voted to thirty-three of the applicants. The following is a summary of some of the cases relieved:

Widow, aged 38, of M.R.C.S.Eng. who practised at Oxford and died in January, 1917. Applicant was left with five children, aged 10 months to 13 years, and with exception of £1,100 capital is dependent on relatives, who cannot do very much. Wants help for the education of the children. Voted £20, and referred to the Guild.

Daughter, aged 56, of M.R.C.S.Eng. who practised in North Wales and died in 1913. Applicant was teaching in Austria when the war commenced, and lost practically all her belongings. Only certain income £21 per annum, and this year has been living on a legacy of £60 left her by a relative. Health has been very indifferent of late. Voted £10, and referred to the Guild.

Daughter, aged 52, of L.S.A.Lond. who practised at London and Eastbourne and died in 1882. Applicant and her mother lived together until the death of the latter in July, 1917, and several small items of income died with her. The applicant has a small school, the profit from which is about £25 a year. Her other income is from investments bringing in about £14 a year. Voted £10 in two instalments.

Daughter, aged 34, of M.R.C.S.Eng. who practised in Yorkshire and Bedford and died in 1906. Applicant has been a chronic invalid all her life, and her brother-in-law has kept her since her father's death, but owing to illness and loss of income he cannot do so entirely now. Voted £18 in twelve instalments.

Daughter, aged 65, of M.R.C.S.Eng. who practised in London and Birmingham and died in 1856. Applicant tries to make a living by sewing, but owing to bad health and the increased cost of living is unable to pay her way. Relieved three times, £35; last time, March, 1913. Voted £12 in twelve instalments.

Widow, aged 36, of L.R.C.P.Édin. who practised in Edinburgh and died in 1916. Applicant was left with four children, aged 3 to 11, with an income of £96 a year. Owing to the increased cost of living she finds it impossible to manage. Relieved once, £12. Voted £15 in twelve instalments.

Widow, aged 59, of L.R.C.P.Édin. who practised at Langley and died in 1909. Lives in own house, which is heavily mortgaged. Endeavours to make a living by taking in paying guests, but, owing to high price of living, is unable to make ends meet. Relieved seven times, £70. Voted £10 in two instalments.

Widow, aged 60, of M.D.Glag. who practised in Perthshire and died in 1907. Her total income from a lodger and other sources £73. Son who helped to keep the home together now in the army. Relieved three times, £22. Voted £10.

M.R.C.S.Eng., aged 48, married, who has practised at Birmingham. Applicant suffers from disseminated sclerosis, and is quite helpless. Only income 10s. a week from relatives. Only son recently elected to an Epsom College scholarship. Relieved once, £18. Voted £26 in twelve instalments.

Widow, aged 47, of L.R.C.P.Édin., who practised at Lochgelly and died in 1913. Has five children, of whom two only are able to assist by providing £95 a year. One son in the army, and no separation allowance. Increased cost of living makes it impossible for her to manage. Relieved twice, £30. Voted £10 in two instalments.

Widow, aged 54, of M.D.Édin. who practised at Newcastle and died in 1896. Applicant left without means. She obtained work, but fractured her leg some time ago, and has been incapacitated since. Has a daughter who is a widow and works as a clerk and helps as far as possible. Relieved three times, £36. Voted £12 in twelve instalments.

M.R.C.S.Eng., aged 47, married, who practised in London and other places. Applicant has suffered from asthma for a number of years. He joined the R.A.M.C., but after a few months was invalided out. Now totally incapacitated from work, and his wife, who had obtained a post, had to give it up to nurse him. All savings practically exhausted. Voted £20, and recommended to apply to another fund, from which a little help has been given.

Subscriptions may be sent to the Acting Honorary Treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

THE Prussian medical court of honour was called upon recently to decide whether doctors should be entitled to reserve to themselves the right to raise their bills if not paid within a certain period. The court decided against this proposal as being derogatory to the dignity of the medical profession.

British Medical Journal.

SATURDAY, JANUARY 5TH, 1918.

THE ASSOCIATION IN 1917.

It has been our custom in the first number of each new year to pass in review the main events of the medico-political world during the preceding twelve months. Present conditions, however, impose brevity upon us no less than upon our correspondents and contributors, and this retrospect must be limited to a few outstanding features only of the work of the British Medical Association in 1917. The full chronicle will be found in the reports of Council, in the records of the proceedings of the Annual Representative Meeting and of the Divisions, and in the report of the conference of Local Medical and Panel Committees. From these it is evident that while the time and energies of medical practitioners have been more and more encroached upon under the grip of war, a number of new problems, as well as of old problems with new names, have had to be handled on behalf of the profession.

Of the topics not immediately related to war, the proposal for a Ministry of Health has, perhaps, attracted most interest, and taken up the greatest share of the time of officers, committee-men, and officials. The story begins with a paragraph in a lay paper last January to the effect that the Local Government Board was about to launch "a little bill" for dealing with maternity and child welfare. It was at once seen that such a measure would have far-reaching effects, and after the matter had been discussed by the committees interested in such questions a special subcommittee was formed to define the policy of the Association. The conclusion was soon reached, and has since been confirmed by the Representative Body and the profession at large, that the only possible method for placing the health administration of the country upon a sound basis would be by the creation of a Ministry of Health—a measure advocated by the Association at intervals during the past fifty years. Communications were opened up with Lord Rhondda, then President of the Local Government Board, and an outline scheme was drafted which formed the basis for further discussion within the Association. This scheme was approved in general terms by the Representative Body, which empowered the Council to go further into the matter, and to present these proposals to the Government on behalf of the medical profession. Since then the Ministry of Health Committee appointed by the Council has held conferences with the promoters of a bill drafted by the National Insurance organizations, and with representatives of the Society of Medical Officers of Health and other professional organizations directly concerned. The original proposals have been examined in the light of recent events, and a revised scheme has been drafted by the committee for submission to the next meeting of the Council. Furthermore, as we noted last week, the Association has been approached by the Minister of Reconstruction, to whom the Cabinet has entrusted the duty of sounding the chief parties interested with a view to the possibility of an agreed bill, and the considered opinion of the Association has now been set out in a memo-

randum, which was forwarded in the last week of the year to Dr. Addison.

During the year several matters arose of great importance to panel practitioners, and these were brought to a head at the annual conference, on October 18th, of representatives of Local Medical and Panel Committees. It was recognized before the meeting that the Insurance Acts Committee of the British Medical Association would have to justify itself once more as the official mouthpiece and central co-ordinating body of the profession in insurance matters. After criticisms had been answered, and explanations given, it became clear that the Committee retained the confidence of the great majority. A proposal that in all negotiations the members of the profession on the panels would be better represented by some separate organization directly appointed by Panel Committees, was lost by 113 votes to 16, while a vote of confidence in the Insurance Acts Committee was subsequently carried by a very large majority. The conference thus reaffirmed the position of the Committee as the authorized spokesman of panel practitioners in central negotiations. This point being settled, the much-discussed regulations for the medical treatment of discharged disabled soldiers and sailors were considered, and it was finally resolved that in view of the decisions of the 1916 conference the Committee had made as good an experimental arrangement as was possible.

With regard to the remuneration for insurance work generally great dissatisfaction was expressed, criticism centring round the constitution of the central pool, and the methods of distribution thereof. It is clear that the medical profession will not be satisfied with the present system of payment as outlined in the explanatory memorandum of the Commissioners (Memo. 229/I.C.) issued in October, 1916, which makes the "insurance day" the unit of remuneration. The conference instructed the Insurance Acts Committee to press for an independent actuarial investigation of the central pool, and to this the Commissioners have since agreed. Other important resolutions related to the just claims of rural practitioners for increased mileage grants. As the result of representations made on their behalf by the Insurance Acts Committee the Commissioners have lately induced the Treasury to authorize an additional grant for 1917, which will permit of an increase in the special payments made to rural practitioners in respect of mileage generally, including extra payments for mileage under the scales laid down for the treatment of temporary residents and for invalided sailors and soldiers. Lastly, the conference demanded, in response to a general feeling throughout the country, that the capitation fee for insurance work should be raised to at least 10s. per annum during the present year. This demand has been placed before the Commissioners by the Insurance Acts Committee. If their negotiations should fail, it is thought that the scheme for collective bargaining approved by the conference may prove a powerful lever at a later date.

A subject prominent throughout the year has been the control of venereal diseases. At the end of January a joint deputation from the British Medical Association, and from municipal corporations, had an interview with the President of the Local Government Board to urge the suppression of the treatment of venereal diseases by unqualified persons, and shortly afterwards the Association issued an important memorandum to local authorities embodying its recommendations for the organized prevention and treatment of these diseases. On March 6th a Venereal Diseases Bill in conformity with the views of the

deputation was introduced into the House of Lords, and later became law. Beyond this the Association has had a hand in fixing the fees medical officers of venereal disease clinics should receive, the scale laid down by the Representative Body having been largely accepted by local authorities throughout the country.

The increasing difficulties of carrying on medical practice in war time have made it necessary for the Association to keep a close watch on Government restrictions as they affect the mobility of doctors, especially those in country districts. Assistance has been given to practitioners in obtaining licences for an adequate supply of petrol; the Ministry of Munitions has been persuaded to make arrangements to facilitate repairs to doctors' cars; and a working arrangement has been entered into for securing a limited supply of carbide for motor lamps for practitioners whose claims can be recommended by the Association. A badge for doctors' motor cars has also been prepared for issue to members of the Association who undertake to use it only when motoring on professional duties. The idea has been cordially approved by chief constables throughout the country, and it is expected that cars bearing this emblem will be relatively immune from the attentions of policemen on the look-out for breaches of the Motor Spirit Restriction Order. It need scarcely be added that this privilege will depend upon the loyal adherence by all users of the badge to their undertaking.

The Central Medical War Committee was brought into being by the British Medical Association, and has been housed, staffed, and financed by the Association, whose machinery has been at its disposal from the beginning. The work of the Committee is widely appreciated throughout the profession, and it is not surprising that the Representative Body decided once more that Association money could properly be expended on this purpose. The influence and prestige of the Committee has undoubtedly increased during the past year. When the military authorities in April made the false step of calling up all medical men under 41, without reference to the statutory professional committees, the Central Medical War Committee and the Committee of Reference made a firm and dignified remonstrance to the War Office, and having a good case their protest was successful. Since that event the position of the professional committees has become more secure, and the Central Medical War Committee is increasingly recognized by Government departments in all matters coming within its purview. Thus the reconstituted National Service Ministry early sought its advice and co-operation in the setting up of the new recruiting boards; while the Committee of Inquiry into the Army Medical Service, whose report on its findings in France has now been presented to the Secretary of State for War, was mainly composed of members of one or other of the three statutory committees recognized under the Military Service Acts.

THE AIR MEDICAL SERVICE.

THE constitution of the Air Council which will replace the Air Board has been fixed and its relation to other great departments of State and to Parliament defined by an Order in Council made in accordance with the Air Forces Act, and gazetted on December 21st. It provides that the President of the Air Council shall be a principal Secretary of State, so that his position in relation to Parliament and the government on the one hand and to the Air Council on the other will be the same as that of the First Lord of the Admiralty

and the Secretary of State for War to Parliament and the government and to the Board of Admiralty and the Army Council respectively. Lieutenant-General Sir David Henderson has been appointed Vice-President of the Council, and there will be eight other members, of whom seven, already nominated, are to be the occupants of certain offices specified in the Order: the Chief and the Deputy Chief of the Air Staff, the Master-General of Personnel, and the Controller of Equipment—these four being appointed by the Crown—the Director-General of Air Craft Production appointed by the Ministry of Munitions, and three other persons appointed by the Secretary of State, of whom two are the Administrator of Works and Buildings, Sir John Hunter, K.B.E. of the Ministry of Munitions, and the Parliamentary Under Secretary, Major J. L. Baird, M.P. hitherto Parliamentary Secretary to the Air Board. A secretary, Mr. W. A. Robinson, C.B. of the Office of Works, and an assistant secretary have been appointed. The Order contains no reference to an Air Medical Service, but it is clear that such a service must at once be established, and it is sincerely to be hoped that the vacant seat on the Air Council may be filled by its Director-General.

The Air Service must be formed at first by combining the air branches of the navy and army into a single service controlled by the Air Council with the new Secretary of State at its head, but recruiting must of course continue. The initiating combination in respect of personnel is to be carried out gradually. At present the officers and men of the two air services are borne on the lists of the navy or army, and the medical officers of air units have been drawn from the one list or the other according to the ascription of the air unit to which they were attached. In this way a certain number of medical officers of both services have gained special experience and have had the opportunity of showing special aptitude for the work. The Air Council will no doubt wish to take these over to form the nucleus of its medical service, and will take care that they lose neither seniority nor prospects of promotion by the transfer.

Part of the work of the Air Medical Service will be of the ordinary kind which falls to be performed by every military medical service, but much of it will be conditioned by the peculiar duties of an air force. Although a considerable proportion of the men enlisted into the Air Service may be for employment on land as mechanics and orderlies at air stations, in repair shops, and in transport and supply, and need not perhaps reach a higher physical standard than men enlisted into other services, it is quite otherwise with the selection of men to be trained for flying. A man who aspires to fly must be submitted to very strict physical examination by the Air Service medical officer before he is sent to be trained; he must be very carefully watched during his training to discover any latent weakness, and after he has been passed as a flyer constant supervision must be kept over the state of his general health, and especially over the condition of his nervous system, to ensure that the perfect adjustment between senses, brain, and muscles, which he must have possessed when he passed the flying tests, is maintained. Many accidents can be traced to a pilot going up when he was not thoroughly fit. The Air Service medical officer in the field or at a camp of exercise must have authority to prevent any man from going up whose quickness of response has deteriorated, and to prescribe the steps to be taken to ascertain whether the deterioration is merely transient, or of such a nature as to require his admission to an Air Service hospital. The duties of such an air medical officer

are therefore in the main clinical, and we would express the very emphatic opinion that in any scheme for an Air Medical Service this fundamental fact should be recognized from the first, and also the further fact that the problems for an Air Medical Service are largely new. The army had an immense body of civil experience and research to draw upon for most of its problems; the same was true of the navy, though in certain directions—vision, for instance—it has had to gain experience which will be of value to an Air Medical Service. But civil practitioners have hitherto had nothing to do with air problems, and physiologists very little. It is therefore incumbent on the Secretary of State for the Air to institute and encourage research into the special physiological and medical problems awaiting solution for the greater efficiency of his service and the saving of lives and equipment. In the Army Medical Service promotion to the higher ranks has very seldom been accorded except to officers selected for administrative posts, who thereupon, as a rule to which there must be very few exceptions, ceased to have any direct personal connexion with clinical medicine and surgery. This may be inevitable to-day when the armies have been so enormously expanded, but it is a misfortune only partly repaired by the appointment and promotion of consultants.

"Fame is the spur that the clear spirit doth raise to scorn delights and live laborious days." If the poet of the puritans could write this, are we to-day to blame a man who, finding the way to the highest positions in his service barred along one road, seeks the other? If it is a misfortune for the Army Medical Service that eminence in clinical medicine and surgery, or in research, very seldom leads to high rank and consideration in the service, it would be a disaster for the new Air Medical Service. We hope Lord Rothermere, when considering the scheme for the Air Medical Service, will give full weight to the scientific side of its work.

THE LOGIC OF THE FOOD POSITION.

"It was so evident that even now he had everything to learn. He did not know that there were physical laws and economic laws, quantities and reactions that all humanity voting *namine contradicente* cannot vote away, and that are disobeyed only at the price of destruction. He did not know that there are moral laws that cannot be bent by any force of glamour, or are bent only to fly back with vindictive violence. . . . He had to defeat the Giants or go under. He was by no means absolutely despairful. In this hour of his utmost failure, with blood and disaster upon his hands and the rich promise of still more horrible disaster, with the gigantic destinies of the world towering and toppling over him, he was capable of a belief that by sheer exertion of his voice, by explaining and qualifying and restating, he might yet reconstitute his power. He was puzzled and distressed no doubt, fatigued and suffering, but if only he could keep up, if only he could keep talking."

This account of the political leader in Mr. H. G. Wells's story, *The Food of the Gods*, brings to a focus a weak point in the economy campaign of the Food Ministry. Nobody can fairly accuse the Ministry of not realizing the importance of appealing to the public at the present juncture; we doubt whether, even at the crisis of the voluntary recruiting campaign, so much printed matter was circulated or so many speeches and lectures delivered as three months of Sir Arthur Yapp's efforts have produced. But no scientific student of this propaganda can fail to notice that it is tainted with the vice of Mr. Wells's politician—an unhesitating faith in rhetoric as the *primum mobile*.

The public are indeed always being preached at or scolded; they are urged to be patriotic, to do their bit to support our gallant fellows at the front; they

are told that what is asked of them is unworthy the name of sacrifice, while the abstemious habits of the Food Controller and his wife (who, we see, at Christmas, "partook of the simplest fare, avoiding even poultry") are chronicled in the daily papers. But what we have looked for and never found in this literature is any sign of faith in the capacity of the working classes to comprehend a reasoned statement. A serious attempt should have been made to render accessible to all the really quite simple scientific facts upon which a system of rationing must be based. There has been no lack of suitable literature. The tract by Professor Wood and Professor Hopkins on *Food Economy in War Time*,¹ and that of Professor Wood on the *National Food Supply in Peace and War*,² are written by acknowledged experts, in non-technical language. The pamphlet *Food and How to Save it*,³ written by Dr. E. I. Spriggs for the Ministry of Food, is a very practical handbook for the housekeeper. It deals with the economical use of food, and has special sections on how to make up the Controller's allowance most cheaply, how it may be done by the well-to-do and those earning good wages, on weekly budgets, and on children's meals. Owing to the date at which it was written it does not now fully apply to present conditions, but it is easy to make the necessary modifications. A Government which can afford to distribute gratuitously millions of copies of a rhetorical sermon might, one would suppose, be able to give a like publicity to the facts of an even graver war problem. As, however, the Government will make no such attempt to educate the nation, the duty devolves upon the medical profession.

In recent issues we have given the heads of a course of instruction which members of the medical profession will, we hope, find useful if called upon to deal with the subject. In the first place, most emphasis should be given to the energy value of food; as Professor Bayliss puts it, "take care of the calories and the protein will take care of itself." This caution is needed because the medical profession in the past has perhaps been rather inclined to dwell upon the problems of nitrogenous metabolism, and the public may have been led to exaggerate the practical importance of this side of dietetics. It should be pointed out that, given an equality of external conditions, the food needs of a worker are completely determined by the muscular exertion he has to put forth. As industrial examples, in addition to those given in previous articles, we may take the following, computed from the valuable data of Slosse and Waxweiler⁴ for Belgian operatives. The mean daily energy value for Belgian weavers (56 observations) was 3,366 calories, for miners (115 examples) 3,604, and for quarry men (49) 4,314. These are net values, allowance having been made for waste in cooking and non-absorption; incidentally, they confirm the conclusion reached in an earlier article that the consumption of food by the English working classes, both before and since the war, was by no means excessive. On these lines the necessity of preferential rationing, whether voluntary or compulsory, and the gross absurdity of all sharing alike can be made intelligible.

In the second place, the fallacy of supposing that brain workers need the same quantity of food as

⁴ *Enquête sur le régime alimentaire de 1,065 ouvriers belges*. Brussels, 1910.

hand workers, can be exposed by an account of Atwater's results.⁶ In this connexion we may refer to an article published in the *Herald* on December 22nd, 1917, under the title "Still Starving at the Ritz." Our contemporary pointed out that while the wealthy might eat their full share of rationed articles they could get in addition an unlimited quantity of the unrationed. It added, "those who imagine that luxurious feeding by the rich does not injure the poor forget that money spent for the benefit of one set of people cannot be spent on others, and also that money only buys labour power in one form or another, and, therefore, labour spent on providing luxuries cannot be spent on the production of the necessities of life." We called attention to the facts some weeks ago, and it seems to us high time that really effective steps were taken to remove a cause of popular discontent. There is, on physiological grounds, no reason why the customers of the Ritz should be unstinted in their consumption of "suprême de sole Jovinillo" or "turbot poché, beurre fondu," the latter delicacy involving (if we correctly interpret what Mr. Chesterton has called a sort of super-French) the use of an article not to be obtained in most retail shops.

Finally, instruction in dietetics will include an account of the way in which external conditions—exposure to cold, journeys to and from the factory, and so forth—increase the energy requirements of the body, and reference must be made to the way in which locally abundant sources of energy—such as potatoes, for example, in some districts—can replace those which are scarce and dear. We believe that on these lines, and with a minimum of technical words and details, it is possible to create a sane public opinion, and we think that the medical profession should lose no time in setting to work. It is hard that this new burden should be placed on the shoulders of over-worked professional men. It is irritating to them to read and hear the rhetorical nonsense emanating from well-intentioned and ill-instructed amateurs. But the scientific man should remember that the irritation he feels at once is, sooner or later, felt by the bulk of his fellow citizens. They may not be able to give scientific reasons for believing that an account of Lord Rhonda's abstinence from turkey on Christmas Day does not help them towards a solution of their own difficulties, but they are conscious that such statements are valueless. It is this smouldering discontent and annoyance which we fear, and we can think of no remedy other than education, and of no educators other than medical men.

THE DEFECTS OF TUBERCULOSIS ADMINISTRATION.

CRUSADES, whether peaceful or warlike, do not always achieve the promises of their initiators, but failure is generally due to lack of co-ordination of the methods of attack. With respect to tuberculosis, the results of combined action do not as yet point to any substantial reduction in the incidence of the disease in crowded areas, although a very considerable number of tuberculous individuals are being restored to working capacity by timely treatment. Does the fault lie with the machinery or with the methods by which the machinery is being employed? The first requirement for the suppression, whether of crime or disease, is detection. The introduction of notification, it was hoped, would enable the presence of tuberculosis in communities great and small to be quickly detected. As at present employed it fails to effect this purpose. The annual returns made by medical officers of health throughout the country bear witness again and

again to the fact that notification is frequently deferred until the final stage of the disease is in progress, and that the greater number of notified cases prove fatal within the two following years. Special attention has been directed to this question by Dr. Ellis, tuberculosis officer for Middlesbrough, where already considerable reforms have been introduced and more trustworthy returns obtained. He has repeatedly pointed out that death registration should in all cases be correlated with notification, not only as a means of obtaining accurate information as to the prevalence of the disease in any given area, but also as an indication of the thoroughness with which notification is being carried out. While it is true that the early diagnosis of tuberculous disease of the lung is not so simple a matter as the recognition of the onset of acute infectious disease, yet to wait for the appearance of bacilli in the sputum is to lose valuable time. Recent correspondence in our columns has made it evident, however, that such delay is by no means unusual. It should be recognized not only by the medical profession but also by local authorities that the merest suspicion of the presence of tuberculosis should be a warrant for notification and examination by an expert, armed with all the means of diagnosis that modern medicine provides. If such examination should prove to be negative no harm will have been done, whereas the prompt discovery of a focus of disease may be the means of saving individual life and usefulness, and the prevention of future infection in the household. To be generally effective such a system must be generally adopted upon uniform lines, and it must be enforced. Without some means of compulsion the present go-as-you-please methods of registration and report will not bring us any nearer to the goal. Only when accurate information is forthcoming as to the incidence and distribution of the disease throughout the country can the various agencies for treatment be economically and intelligently applied. Not only central control but abundant powers, delegated to local authorities, are needed if the existing machinery is to yield the results for which it was originally set up.

THE FOOD REQUIREMENTS OF MENTAL WORKERS.

WE publish elsewhere (p. 37) a letter by Dr. Mercier on the food requirements of sedentary workers, which, like all he writes, is interesting, and, from our point of view, the more opportune, because it affords an opportunity of once more stating certain facts which do not yet seem to have received the general appreciation they deserve. Dr. Mercier's letter, indeed, rather provokes the question, *scire tuum nihil est, nisi te scire hoc sciat alter?* About the necessity of vitamins in a diet there can be no two opinions. A diet, superabundant in calories, might be fatally insufficient through a lack of vitamins. But as war flour is an adequate source of antiscorbutic vitamins, and the fresh vegetables, which the Food Controller urges us to consume, are well supplied with antiscorbutic vitamins, no diet likely to be devised for the civilian population will be defective in these particulars. Hence we did not devote space to enlarging upon the obvious. It is also true that a modicum of protein in the diet is necessary to mental as to other efficiency, although we had forgotten that the credit of demonstrating this belonged to Dr. Mercier; but we were mindful of the evidence produced by Atwater, Benedict, and Carpenter, showing that the intensity of metabolism is not appreciably affected by mental work. Atwater and Benedict,¹ when speaking of their study of the effects of mental work in calculating and studying a German treatise on physics for eight hours a day, say: "In intensity and amount it was such as would hardly be equaled by a person not accustomed by long training to reasonably severe mental effort. Yet, as previously noticed, it exercised no apparent

⁶ BRITISH MEDICAL JOURNAL, December 15th, 1917, p. 800.

¹ Bulletin 136, p. 191.

effect on the metabolism of matter or energy, the results of the period agreeing in all essential particulars with those of the period in which the subject rested." We do not think there is any evidence that the requisite quantity varies with the consumer's intellectual effort. A caterer who, on the basis of available foodstuffs, drew up a diet scale providing sufficient calories but insufficient protein would need to exercise considerable ingenuity. If we take care of the calories the protein will take care of itself. Lastly, a recognition of the influence of external conditions upon the rate of heat loss, and therefore upon the need for energy in the food, is surely implicit in any argument based upon calories at all. The figures we provided were deduced from average experience, and like all averages may be inapplicable in particular circumstances. This is the real case against any paper scheme of rationing, but, on that point, Dr. Mercier's quarrel is not with us, but with the Food Controller or the U boats.

THE PULSE PRESSURE TEST BEFORE OPERATIONS.

A SIMPLE and reliable test for the estimation of the reserve power of the cardio-vascular system in cases in which an operation is proposed would be a valuable addition to available methods of clinical prognosis. A test of this kind depending on the behaviour of the pulse pressure after exercise has been proposed by Cashman,¹ who gives blood pressure and pulse charts and a number of illustrative cases, including some in which, as a result of this test, operative interference was refused or carried out under local or spinal anaesthesia so as to subject the circulatory system to the least possible strain. In a normal person exertion calls forth a compensatory response on the part of the cardio-vascular system with a rise of both the systolic and diastolic blood pressures; but as the diastolic pressure rises less than the systolic, there is an increase in the pulse pressure, or the difference between the systolic and diastolic pressures, as compared with that before the exertion. On the other hand, a fall in the pulse pressure, whether due to a fall in the systolic pressure or to a rise in the diastolic pressure, shows that there is a poor response to mild strain on the part of the cardio-vascular system, and is usually accompanied by breathlessness, dizziness, or fatigue. This is often seen in visceroptosis, prolapse of the uterus, and gall bladder disease, and may be due to a damaged myocardium or cardio-vascular system that is working with so little reserve power that it may fail if subjected to sudden strain. In practically all operations the cardio-vascular system is exposed to strain, varying in different instances, and the risk of death from cardiac failure is considerable in cases in which this test shows diminution of the pulse pressure on mild exertion. The test is carried out as follows: The pulse-rate and blood pressures are taken in the recumbent and in the standing position, then the patient walks rapidly or uses dumb-bells, and the pulse-rate and blood pressures are again taken in the standing and recumbent positions. In normal persons the systolic pressure rises on standing and after exercise, whereas in cases of cardio-vascular debility the systolic blood pressure falls on changing from the recumbent position. The increase or rise of the pulse pressure in healthy persons and its diminution or fall in cardio-vascular insufficiency have already been mentioned. In cases with gross irregularities in the force of the heart the test is difficult to apply. It appears to have been independently suggested by Lankford.

THE ALLEGED INCREASE OF CANCER.

IN the *Journal of Cancer Research* (July, 1917) Professor W. F. Willcox, of Cornell University, publishes an interesting statistical paper on the alleged increase of cancer. He discusses the various explanations which have been put forward to account for the recorded increase of cancer

mortality in all civilized countries, and concludes that "the cumulative evidence that improvements in diagnosis and changes in age composition explain away more than half, and perhaps all, the apparent increase in cancer mortality rebuts the presumption raised by the figures, and makes it probable, although far from certain, that cancer mortality is not increasing." The most important addition to existing data contained in Professor Willcox's essay is an extension down to 1913 of the tabulation of deaths from cancer in Frankfort, which was used by King and Newsholme in their well-known paper of 1893. This tabulation supports the original views of King and Newsholme, in that the increase has continued to affect only "inaccessible" cancer in both sexes, the rates for "accessible" cancer being stationary. In other respects the author follows familiar lines, the difference between different workers being chiefly a question of the emphasis put upon particular arguments. In one or two respects Professor Willcox seems to attribute rather more novelty to his criticisms than they possess. We think that all vital statisticians are thoroughly familiar with the fact that comparisons in terms of a standard population are affected by the choice of standard. The discussion has turned not on the fact, but upon how to avoid fallacious interpretations. Professor Willcox does not mention the most recent contribution to the subject, that of Pearson and Tocher,¹ who suggest that when the question is whether two samples are compatible they should be reduced to that standard population which makes it least likely that the two samples could have arisen therefrom. They show how to determine such a standard, point out practical difficulties in its application, and propose another and more general treatment of the problem, which is of importance, and avoids the ambiguity of the standard population method. It should also be noted that many other authors have provided statistical evidence of the association between cancer death-rates and facilities for diagnosis. For instance, Greenwood and Wood found for American cities a correlation of 0.23 between the death-rate from cancer and the presence of a good medical school, the population being kept constant by the method of partial correlation.² Maynard³ also went into the question of diagnosis in connexion with American data.

FLIES IN WINTER.

WHAT happens to flies in winter? This question has long vexed entomologists and sanitarians, and is of special interest now that we have a vast army living under active service conditions, and exposed to fly-borne diseases. Many observers maintain that adult flies are capable of hibernation in warm and quiet corners. According to this view, a few flies in the fully developed form go into winter quarters towards the close of October, and emerge under the spell of the warm spring days to set about the business of propagating their kind. Captain R. P. McDonnell and Staff Sergeant T. Eastwood, R.A.M.C., have recorded in the *Journal of the Royal Army Medical Corps* some observations which tend to show that flies pass the winter in the larval stage, and that the hibernating adult fly is a myth. Their investigations thus support the minority opinion that all flies die off about October or November, and that the species is preserved by the careful selection on the part of the female fly of a suitable hatching ground for her eggs out of harm's way. But those who hold this view have suggested that the ova remain unchanged throughout the winter, and only hatch out into larvae when summer approaches. Captain McDonnell and Staff Sergeant Eastwood made thorough examination of many manure dumps and disused trench latrines in order to test their hypothesis that the flies' eggs deposited in such places during late autumn are the source of the next

¹ *Biometrika*, 1916, xi, 163.

² *Journ. Hygiene*, 1914, xiv, 89.

¹ Z. Cashman, *Amer. Journ. Med. Sci.*, 1917, cliv, pp. 476-489.

year's plague of flies, and, further, that the hatched-out larvae in a dormant state persist all the winter, and come to the surface in spring or early summer. On March 3rd, 1917, after weeks of bitterly cold weather, living fly larvae were found three feet down in a heap of old manure which had lain untouched since October, 1916, and was covered with grass and leaves. Further evidence of the same kind was collected, but the authors rightly refuse to draw definite conclusions from the few preliminary and isolated observations so far made. The practical bearing of these inquiries is evident. If the larvae and pupae of flies are proved to survive in considerable numbers in manure heaps during winter, then manure heaps must be looked on as a source of danger at all seasons of the year. It is, we believe, well established that all the adult individuals of many species of insects do die off during the winter, the race being continued by eggs carefully hidden in a suitable place with a stock of food for the larvae. At the same time there is no doubt that adult flies may be seen on the wing in many warm kitchens all through the winter, and it does not seem to have been proved that these are incapable of laying eggs in the spring.

THE VENEREAL DISEASE DISPENSARY SYSTEM IN GERMANY.

At the annual meeting of the German Society for Combating Venereal Disease, held on June 22nd, 1917,¹ in Mannheim, the sole topic of discussion was the dispensary system, which has encountered much criticism and opposition. The physician in charge of this system in Metz, Dr. Max Müller, outlined the aims of the dispensary with regard to the continuity of treatment of syphilis. Recovery could be assured only by prolonged treatment and supervision of the patient, and it was one of the functions of the dispensary to step in when the patient, against the advice of his doctor, absented himself. The dispensary was to be a link between the patient and his doctor, shepherding the wayward patient back to his doctor for treatment. Yet the dispensaries, he admitted, had not been received by the medical profession with the "joyful and general acclamation" so good a social reform deserved. Many objections had been raised. It was feared that the dispensaries would interfere with the relations between patient and doctor, and would fetter scientific progress by petty regulations. These were fears which the tact of the dispensary chief would have to allay; he should avoid criticizing the doctor's treatment. Another objection was the breach in the confidential relations between the patient and his doctor threatened by the intervention of the dispensary. The doctors were, however, to be under no compulsion with regard to the dispensary, as had been threatened, and the dispensaries, on the other hand, would shun autocratic ways. In return it was hoped that the doctors would abandon their opposition, which was not appreciated by the general public, which was inclined to overlook the ethical objections of the medical profession to a social reform, and to see in its opposition a selfish motive. In the discussion after this speech it was agreed that the dispensary system must be regarded as an established institution, and that it remained for its adherents to labour for its developments along the best lines. Finally a motion was passed, without dissent, to the effect that all doctors should help in the campaign against venereal disease, and that those in particular who had already utilized the dispensary system with good effect should enlighten their patients as to its aim and value. It was recognized that the doctors should be tactful in committing unwilling patients to the dispensary, and that the campaign against venereal disease could be successful, notably in regard to the dispensary system, only with the co-operation of as many doctors as possible. It was therefore essential for the insurance societies to work in harmony with the medical

profession. It was necessary also that unqualified practitioners should not be allowed to tamper with venereal disease, and that treatment by correspondence and public touting for patients should be prohibited by law.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

THE alphabetical rubrics in the current part of the *New English Dictionary* run from stillation to stratum, and the medical terms from stillbirth to stratification, although, of course, the last-named word has other than medical meanings. The term stillborn is defined as "born lifeless, dead at birth, abortive," and no hint is given that it is ever employed in any other sense, although as a matter of fact several recent textbooks of obstetrics regard it as synonymous with asphyxia neonatorum, and one (R. W. Johnstone's) adds: "Stillbirth is not the same thing as the child's being born dead, although death may supervene if prompt treatment is not applied." It is somewhat curious that the first recorded use of the word stillborn in English seems to have been in the figurative sense. It is in Shakespeare's *Henry IV*, Part II: "Grant that our hopes (yet likely of faire byrth) should be stillborn." Stimulant has three physiological or medical meanings, namely: (1) Something that temporarily quickens some vital process; (2) alcoholic drinks; (3) something that excites an organ to its functional activity. The same three meanings run through the other allied terms such as stimulate, stimulating, stimulation, and stimulus. Stint is an interesting word etymologically, and it is sometimes used with the medical meaning of to check or staunch—for example, a bleeding. The editors of the Dictionary are so careful, as a rule, to give every medical usage of ordinary terms, that one is surprised not to find stirrage given as an occasional synonym of quickening in the sense of the feeling of fetal movements. The employment, however, of stirp, with its modern meaning in eugenics, is chronicled; and stirrup in its surgical application is referred to. Among the rarer medical terms are stithy, the anvil bone of the ear and a disease incident to horses and oxen; stive, the eyeball or the pupil; and stonepock, a hard suppurating pimple. Commoner medical words are found in stomacace, stomatic, stomatitis, stomato- in various compounds, storax, strabism and strabismus, strabotomy and stramonium. Stone has some curious semi-medical significations, such as the equivalent of a urinary calculus or of a gallstone, of a testicle, or as an intensive corresponding to completely, as in stone-blind, stone-dead, and stone-dumb. And so, notwithstanding the vicissitudes of these times, this great national undertaking, the *New English Dictionary*, goes on its way towards a successful, if to a somewhat retarded, conclusion, and the editors are to be congratulated, one and all, on their indefatigable lexicographic labours.

SUNLIGHT, FOLIAGE, AND AIR PURIFICATION.

A PAPER on the influence of sunlight on the formation of nitrites from nitrates in aqueous solution and on the assimilation of nitrites by green leaves, read at the last meeting of the Royal Society by Professor Benjamin Moore, contains several points of general interest. He finds that when green leaves are immersed in nitrate solution comparatively little nitrite accumulates, showing that nitrites are rapidly absorbed by the green leaf. Nitrates taken up by plants from soil would, in the presence of sunlight, be changed to nitrites, which are much more reactive. This indicates that the early stages of synthesis of nitrogenous compounds are carried out in the green leaf and aided by sunlight. Dilute solutions of nitrates exposed either to sunlight or to a source of light rich in light-energy of short wave-length (such as light from the mercury arc) are converted into nitrite. The fact that the interposition of a layer of glass between the source of light and the solution of nitrate

¹ *Med. Klin.*, July 29th, 1917.

greatly slows the reaction, shows that the most effective rays are those of short length. Rain water preserved for a considerable time contains no nitrites, but freshly collected rain water or dew always contains a mixture of nitrites and nitrates. Air bubbled through distilled water free from nitrite and nitrate gives a mixed reaction afterwards when the water is tested for nitrites and nitrates, showing presence of both forms of oxides of nitrogen in air. There is no hydrogen peroxide or ozone in air at surface level. The fresh odour in open air, commonly referred to as "ozone," is probably nitrogen trioxide, which at high dilutions has the odour of ozone. The oxides of nitrogen are probably formed by the action of sunlight, rich in ultra-violet rays, upon air and aqueous vapour in upper regions of the atmosphere. Professor Moore concluded by drawing attention to the importance of these actions of light in purification of air and water and enrichment of soils and waters by the continuous supplying of matter essential to organic growth, the energy of which, like that for the upbuilding of non-nitrogenous organic compounds, comes from sunlight.

THE PHYSIOLOGICAL PROBLEMS OF THE ILLUMINATING ENGINEER.

THE young profession of illuminating engineering has never hesitated to enlist the help of the ophthalmologist, for, notwithstanding all rules and formulas and readings of photometers, the ultimate verdict on the lighting of any place or building is based on the impression received by the eye. *Solus oculus est iudex*. This was pointed out in Mr. A. P. Trotter's presidential address to the Illuminating Engineering Society, when it was stated that it would be useful if more work were done, or at least more literature made accessible, on the physiology of vision so far as concerns the relation of light flux to visual perception. Mr. Trotter pointed out that the range of luminous stimulus to which the eye could respond was enormous extending from illuminations of 0.0001 of a foot-candle on the darkest night to 5,000 or more foot-candles in summer sunshine. There must be some intricate provision over and beyond the mere contraction of the pupil—perhaps a chemical change in the retina, or an inhibition of the optic nerve, or a compensatory reaction or opposing activity in the brain—to explain the automatic adjustment of control which permitted so sensitive an organ as an eye to accommodate itself to such great changes in the external stimulus. If the physiologist could inform the illuminating engineer further with regard to that quantitative control it would be of assistance in many ways. Mr. Trotter suggested that illuminating engineers should give some attention to experimental and observational psychology, so that the various factors involved in sense impressions could be disentangled and dealt with one by one.

THE Royal Dental Hospital, Leicester Square, has received a donation of £250, being the amount allocated to the hospital by the trustees of the late Leopold Salomons, Esq.

THE Scottish Women's Hospitals have done excellent work in France, in Serbia, and in Corsica for the Serbians, in Salonica, and Rumania, as has been noted from time to time in these columns. The committee has now published a second *Thistle* souvenir book, a miscellany of stories, verse, and pictures, intrinsically worth more than the price (Glasgow and London: J. Horn, Ltd. (and Menzies); pp. 104, 1s. 6d.) at which it is sold. The first page reproduces in facsimile a letter from M. Poincaré, who has not forgotten that he is Lord Rector of the University of Glasgow. In it he expresses his gratitude "to the courageous Scottish women for their inexhaustible charity and for the indefatigable devotedness they show to the wounded soldiers of the allied countries." Miss Mellroy is to be congratulated on having got about her so long a list of distinguished contributors and on the good appearance the new number of the *Thistle* makes.

THE WAR.

TREATMENT OF WOUNDS OF WAR.

WE gave some account, a short time ago, of the results reached by the Inter-Allied Surgical Conferences held in March and May, 1917. A third conference, held in November, 1917, was attended by delegates of America, Belgium, Great Britain, France, Italy, Japan, Portugal, and Serbia. It reached a number of conclusions which are of general interest, some of them to surgeons at the front, others also to those serving at hospitals at the base or at home.

Wounds of the Thorax and Abdomen.

(1) In wounds involving both the thorax and abdomen the special factor is the wound of the diaphragm; the wounds of the thoracic and abdominal organs do not present any special features from the anatomical point of view. (2) Hernia of the abdominal organs is difficult to recognize clinically. Radioscopic examination showing displacement of the heart to the right is an element in diagnosis which should be taken into account, especially with haemothorax of the left side. (3) Operation is indicated in almost all cases, the exception being the case of a very small projectile involving only the upper part of the abdomen, especially on the right side. Independently of indications for operation afforded by the thorax and the abdomen, perforation of the diaphragm is in itself sufficient to call for suture. (4) Operation by the thoracic transpleural route presents great advantages both for the inspection of the lesions and for the treatment of the pleural cavity and the diaphragmatic wound (suture). It permits also the treatment of lesions of the subdiaphragmatic abdominal organs, whether herniated or not. (5) Cases occur in which a separate laparotomy may be indicated. (6) Thoracic-laparotomy allows of the treatment of both the thoracic and abdominal lesions on a large scale and through a single incision.

Fractures involving Joints.

(1) The aseptic course seen by osteo-articular lesions in which operation is performed early (within ten to twelve hours) clearly indicates that the surgical treatment of fractures involving joints should aim at the maximum of conservatism. (2) Comminuted fractures of the epiphysis and shaft are now amenable to thorough cleansing and curettage, followed by primary suture. (3) Fractures of the epiphysis and shaft which are partial or in T form are, according to circumstances, amenable to arthrotomy with reposition, or to arthrotomy with limited excision of bony fragments (partial atypical resection) followed by primary suture. (4) Primary resection is indicated only in exceptional instances: (a) in the case of bony lesions, when it should be performed only in very comminuted fractures of the articular extremities; experience proves that it is more likely to be required at the hip or shoulder than in the knee, elbow, or foot; (b) primary resection in doubtful cases in order to obtain a better functional result should give place to conservative methods (arthrotomy with removal of fragments of bone, partial atypical resection). Bad functional results are amenable to late orthopaedic resection, which will generally be done under better conditions than a primary resection. (5) The indications for primary amputation are crushing of the limb with destruction of the principal arterial trunk. (6) Immediate active mobilization appears to be an indispensable part of operative treatment, and seems to have given better results than those following immobilization (Willems). (7) Resection may still be necessary in the treatment of infected articular fractures.

Treatment of Chronic Osteomyelitis.

(1) The mechanism of infection is the same as that of infection in other war wounds; it spreads in two ways: (a) by continuity through the medullary and compact tissue, and (b) to a distance along fissures. (2) The spread through the bony tissue is generally slow and limited. Among the earliest germs to spread are the streptococcus, the staphylococcus, the enterococcus, and, more rarely,

anaerobic organisms. The germs most often found in the flora of subacute or chronic suppuration of bones are the streptococcus, staphylococcus, enterococcus, and the pneumobacillus. (3) The treatment of chronic osteomyelitis should above all things be preventive; it does not differ from the treatment of the seat of fracture. (4) At the present time the treatment of established osteomyelitis is purely surgical; it should be undertaken early and consists essentially of (a) free opening up of the seat of fracture; (b) careful search for all sequestra and foreign bodies, and their removal; (c) free laying open of all cavities. (5) This having been done one of two alternative methods may be followed: either (a) immediate closure of the wound, completed by an autoplasmic operation, or (b) chemical sterilization of the wound, secondary autoplasmia to fill up the bony cavity, and then suture. The second method is that most generally applicable.

Late Results of Fractures of the Thigh.

(1) Speaking generally, the end results of the treatment of fractures of the thigh are poor. This is due to the extent of the lesions, to insufficient reduction and retention, and, above all, to infection of the seat of fracture. (2) The late results of fractures in the upper third, and still more in the lower third of the femur, are those which leave most to be desired. (3) The late complications most frequently met with are (a) infections producing chronic osteomyelitis; (b) deformities due to incomplete reduction (shortening, rotation, and angular union); (c) very rarely defective consolidation, or functional loss of power having an articular, muscular, or nervous origin. (4) Of these deformities, shortening is the most common, and the only one which is not always avoidable (loss of bone). (5) Rotation and angular union are most often due to inefficient surgical treatment. (6) Primary sterilization is the principal object to be sought; its insufficiency is the essential cause, direct or indirect, of the defective results. The slow progress of, and the difficulties encountered in treating, prolonged infections make it less possible to ensure retention of the fragments. (7) Primary suture of the wound and secondary suture after cicatrization, transforming an open fracture into a closed fracture, have a determining influence on the remote results of treatment of fractures of the thigh. (8) Joint stiffness, very frequently observed in the knee, and stiffness of the hip and the foot, either separately or in combination, can be prevented by early mobilization. (9) Adhesions of muscles to the callus are the cause of many functional troubles which may necessitate surgical operation to free them. (10) Trophic complications (muscular atrophy, oedema, vasomotor disturbances) play a very important part and should always receive early and persistent treatment. (11) Very pronounced deviations, attended or not by osteomyelitis, are amenable to osteotomy; when there is concomitant osteomyelitis resection of the callus is generally indicated.

Wounds of Nerves.

(1) Operations on nerves for war wounds have so far given relatively poor results. Partial lesions give a larger percentage of good results than total lesions. (2) The mediocrity of the results is due chiefly to operation at too late a period. (3) Operation should never be undertaken in the presence of suppuration. (4) The three principal causes of want of success in late operations on nerves are (a) sclerosis of the peripheral end which must increase with the lapse of time; (b) too wide an interval between the two ends; (c) the intensity and duration of suppuration. (5) Retraction of tendons, ankylosis of joints, and ischaemic muscular sclerosis all tend greatly to diminish the value of the functional result. The joints ought from the first to be put in an appropriate corrective position. (6) Primary suture of the nerve, which is rendered possible by the methods now in use for the disinfection of wounds, tends considerably to improve results in respect of the frequency, the rapidity, and the degree of functional recovery. (7) Even when the operation is unsuccessful, primary suture maintains the ends of the nerves in an anatomical position which greatly facilitates later operation. (8) Functional recovery occurs slowly; it requires many months and even years, and this fact must be kept in mind in estimating the final degree of disability.

Secondary and Late Complications of Wounds of the Brain.

(1) The effect of the documents collected* is to show that though secondary complications of cerebral wounds are relatively frequent, late infectious complications are much more rare than was supposed. (2) Organic disorders consecutive to wounds of the brain (hemiplegia, monoplegia, aphasia, visual disturbances, etc.) frequently show a tendency to improve. Their treatment belongs to the domain of neurology. (3) Late epileptic attacks of a Jacksonian character may be benefited by surgical operation—the removal of a cause of compression, of foreign bodies, or of fragments of bone. It is not advisable to operate on account of one or two isolated attacks of Jacksonian epilepsy, for they may be due to an attack of encephalitis from which recovery may take place, and upon the course of which surgical operation can have no influence. Epileptic attacks, except in cases where a foreign body or a fragment of bone is present, do not call for any fresh surgical operation. Where there is hypertension of the cerebro-spinal fluid, lumbar punctures controlled by the manometer may be useful. (4) Late cerebral abscesses, diagnosed and differentiated from non-suppurative encephalitis, ought to be operated upon after accurate clinical localization by the surgeon and the neurologist. After an exploratory puncture and taking care not to destroy protective adhesions, the abscess should be opened and its sterilization tested periodically by bacteriological examination. (5) Late localized meningitis and encysted meningeal abscesses ought to be operated upon. (6) The present treatment of generalized meningitis is usually ineffective. The most rational means of treatment appears to be repeated lumbar puncture. (7) Cerebral hernia with abscess should be operated upon and the abscess drained. It seems preferable, in order to avoid the possible diffusion of a local infection, not to perform lumbar puncture during the acute febrile phase which occurs in some cases of cerebral hernia. When the evidences of infection observed at the onset have diminished, lumbar punctures, by diminishing intracranial hypertension, may favour the reduction of the hernia. Resection of a hernia is an operation only justifiable when local necrosis occurs or meningocele is present. (8) Intracerebral foreign bodies which are determining attacks of encephalitis, epileptic attacks, or an abscess, should be removed. Foreign bodies which are well tolerated ought, it would seem, to be left alone. (9) The facts collected show that cranioplastic operations performed with an aesthetic object are specially indicated when the loss of substance is in the frontal region. From the point of view of cure they are only justifiable in cases in which the distensibility of the scar is the only discoverable cause of the symptoms observed. From the prophylactic point of view the risk of cranial injury of the trephined region later on may be an indication for operation. In every case the surgeon should make sure that there is no contraindication to operation afforded by any nervous trouble, by any chemical or cytological alteration in the cerebro-spinal fluid, or by papillary stasis. (10) The best prophylactic treatment of secondary or late infectious complications is by methodical disinfection and primary sterilization of the intracerebral traumatic foci.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died on Service.

Surgeon Probationer H. M. Macpherson, R.N.V.R.

Prisoner of War.

Surgeon Probationer P. A. Faichney, R.N.V.R.

ARMY.

Died of Wounds.

COLONEL C. C. FLEMING, D.S.O., R.A.M.C.

Colonel Charles Christie Fleming, D.S.O., R.A.M.C., died, aged 53, on December 24th, 1917, of wounds caused by a bomb on the previous day. He was the son of the

* Of 6,661 old cases of trephining in hospitals in regional neurological centres in France the number of epileptic attacks partial or general observed was 675 (10.14 per cent.); the number of cases of cerebral abscess was 94 (1.41 per cent.); of old meningitis 32 (0.48 per cent.); and cases of late cerebral hernia 54 (0.81 per cent.); among these old cases of trephining, there were 83 deaths (1.24 per cent.), and one case only of sudden death.

late Deputy Surgeon-General Andrew Fleming, was born on November 6th, 1864, and educated at Edinburgh University, where he graduated M.B. and C.M. in 1888. After filling the posts of resident physician and resident surgeon in the Edinburgh Royal Infirmary, and of resident physician in the Edinburgh Royal Hospital for Sick Children, he entered the R.A.M.C. as surgeon-lieutenant on January 30th, 1892, becoming surgeon-captain on January 30th, 1895, and major on January 30th, 1904, and retiring on October 29th, 1910. After his retirement he acted for a time as secretary to the Scottish branch of the British Red Cross Society. He also joined the Reserve of Officers, and rejoined for duty on April 17th, 1915, in his old rank of major. During the war he had risen to colonel, and was A.D.M.S. to the Highland Division when he met his death. He served in the Nile campaign of 1898 as senior medical officer in the operations on the Upper Atbara, in the action at Gedaref, and in the defence of Gedaref; was mentioned in dispatches, and received the medal, the Egyptian medal, and the D.S.O. He also served in the South African war from 1899 to 1902, when he took part in the advance on Kimberley, including the actions of Belfont and Magersfontein, in the relief of Kimberley, and in the operations in Cape Colony and in the Orange River Colony, and received the Queen's medal with five clasps and the King's medal with two clasps.

CAPTAIN N. MCG. SMITH, R.A.M.C.

Captain Norman McGaan Smith, R.A.M.C., was reported as having died of wounds, in the casualty list published on December 22nd, 1917. He was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1915, took a temporary commission in the R.A.M.C. soon after, and was promoted to captain after a year's service.

Died on Service.

CAPTAIN W. E. GIBBONS, M.D., R.A.M.C.

Captain Wilfred Ernest Gibbons, R.A.M.C., died at a base hospital on December 21st, 1917, after a short illness following an operation. He was the son of Mr. John Gibbons of Mossley Hill, Liverpool. He received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1896, and M.D. in 1900. He had held the office of house-surgeon to the Edinburgh Royal Infirmary, and subsequently became assistant to Dr. Maclaren, the senior surgeon at the Carlisle Infirmary. He settled in practice in Leicester in 1900, and was late chairman and honorary secretary of the Leicester and Rutland Division of the British Medical Association. He took great interest in sports, and on several occasions represented his university at association football. He married in 1901, and is survived by his widow and two children. In 1908 he joined the Territorial Force, and was mobilized with his unit, and had been on the staff of the base hospital since November, 1914.

Accidentally Killed.

CAPTAIN H. M. SPOOR, M.C., R.A.M.C.

Captain Herbert Mather Spoor, M.C., R.A.M.C., was reported as accidentally killed, in the casualty list published on December 29th, 1917. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1908, and then went into practice at Stoke, Rochester, where he held the appointment of superintendent of the Hoo isolation hospital. He joined the R.A.M.C. as a temporary lieutenant on April 17th, 1915, was promoted to captain after a year's service, and received the Military Cross on September 26th, 1917.

Wounded.

Captain R. G. Burnard, Australian A.M.C.
 Captain W. C. Douglass, R.A.M.C. (temporary).
 Captain F. G. Flood, M.C., R.A.M.C. (S.R.).
 Captain J. R. Forde, R.A.M.C. (temporary).
 Captain L. R. Hill, R.A.M.C. (temporary).
 Captain E. H. Lawson, R.A.M.C. (temporary).
 Captain D. M. Moffatt, M.C., R.A.M.C. (temporary).
 Captain J. E. S. Smith, R.A.M.C. (T.F.).
 Captain C. J. Timms, M.C., R.A.M.C. (temporary).
 Captain W. K. Turner, Canadian A.M.C.
 Lieutenant G. Gordon, R.A.M.C. (temporary).
 Lieutenant S. G. Johnson, R.A.M.C. (temporary).

Formerly Reported Wounded, now Reported not Wounded.

Captain O. Matthews, Australian A.M.C.

Missing.

Captain G. A. D. McArthur, R.A.M.C. (temporary).
 Lieutenant T. F. Ryan, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Cavanagh, Rev. Bernard C. F., son of Dr. Cavanagh of Dublin, died of wounds in Palestine on December 21st, 1917. He was born at Limerick in 1866, educated at Crescent College, Dublin, ordained in 1890, and had worked for twenty years as a Redemptorist missionary before he joined the army as a chaplain.

Crawford, Dunlop, Second Lieutenant Royal Engineers, only son of the late Dr. John Kerr Crawford of Kilwinning, died of wounds in East Africa on December 10th, 1917, aged 28.

Elliott, H. C., Lieutenant Royal Engineers, second son of Dr. Christopher Elliott of Clifton, died at a base hospital on December 20th, 1917, of wounds received on December 8th.

Steyn, Stephen Sebastian Lombard, Lieutenant Royal Field Artillery, son of the late Dr. G. H. Steyn, killed in December, 1917, aged 26. He was educated at the Diocesan School, Rondebosch, South Africa, and at the University College, Oxford, where he was a Rhodes scholar of 1909. He was a noted Rugby football player, having played at three-quarter both for Oxford and for Scotland in 1911 and 1912. He got his commission on December 8th, 1914.

MEDICAL STUDENT.

Chalmers Cowan, Philip, Captain Manchester Regiment, attached Royal Flying Corps, is reported missing since November 8th, 1917, when he took part in an air combat in France. Captain Cowan was a second year medical student of Trinity College, Dublin, when he joined the Manchester Regiment in August, 1914, from the Dublin University O.T.C. He was promoted captain in October, 1916, and shortly afterwards joined the Royal Flying Corps. He was in his twenty-second year and was a son of Dr. P. C. Cowan of Ailesbury Road, Dublin.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

In connexion with the New Year long lists of appointments, awards, and promotions were published in special supplements to the *London Gazette* on December 31st. The honours mentioned have been awarded to the following medical officers, all of whom belong to the A.M.S. or R.A.M.C. unless otherwise indicated:

Naval Awards in Recognition of Services during the War.

K.C.B. (CIVIL).

Surgeon-Generals: Wm. Henry Norman, C.B., R.N., George Lenthal Cheatle, C.B., C.V.O., R.N.

C.B. (CIVIL).

Surgeon-Generals: Arthur Edmunds, R.N., Wm. W. Fryn, R.N., James Lawrence Smith, M.V.O., R.N.
 Deputy Surgeon-General Daniel Joseph Patrick McNabb, R.N.

C.M.G.

Fleet Surgeon E. H. Meaden, R.N.

D.S.O.

Staff Surgeon Henry Cooper, R.N.

For Valuable Services Rendered in Connexion with Military Operations in the Field.

C.B. (MILITARY DIVISION).

Surgeon-Generals: Richard Henry Stewart Sawyer, C.M.G., Henry Neville Thompson, C.M.G., D.S.O.
 Colonel and Honorary Surgeon-General Bruce M. Skinner, C.M.G., M.V.O.

Colonels: Charles Mackie Begg, C.M.G., N.Z.M.C., Robert Hammill Firth, Anthony John Luther, Foster Reuss Newland, C.M.G., Alexander Dunstan Sharp, C.M.G., James Matthew Forrest Shine, Alfred Sutton, C.M.G., A.A.M.C., Hugh Champneys Thurston, C.M.G., James Barnett Wilson, C.M.G.
 Lieut.-Colonel and Brevet Colonel (temporary Colonel) Frederick Smith, C.M.G., D.S.O.

Temporary Colonels: Sidney Maynard Smith, Alfred Henry Tubby, C.M.G.

Lieut.-Colonel and honorary Colonel Charles Joseph Trimble, C.M.G.

Lieut.-Colonel (temporary Colonel) Thomas Finlayson Dewar.

Lieut.-Colonel (acting Colonel) Arthur Russell Aldridge, C.S.I., C.M.G.

G.C.M.G.

Temporary Surgeon-General Sir George Henry Makins, K.C.M.G., C.B.

K.C.M.G.

Surgeon-General William Grant Macpherson, C.B., C.M.G.
Colonels and honorary Surgeon-Generals: James Murray
rwin, C.B., James Maher, C.B.
Temporary Colonels: Thomas Crisp English, C.M.G.,
James Purves Stewart, C.B.

C.M.G.

Colonels: George Walter Barber, D.S.O., A.A.M.C., Robert
James Blackham, C.I.E., D.S.O., Ernest William Bliss, D.S.O.,
Edward George Browne, C.B., Robert Rupert M. Downes,
A.A.M.C., Philip Cecil Harcourt Gordon, Alfred Ernest C.
Kibble, D.S.O., Charles Joseph MacDonald, Samuel Guise
Moore, C.B., Charles William Profeit, D.S.O.

Temporary Colonel (Lieut.-Colonel R.A.M.C.T.F.) William
Pasteur.

Lieut.-Colonel and Brevet Colonel (temporary Colonel)
Howard Ensor, D.S.O.

Lieut.-Colonels (temporary Colonels): Arthur Thomas White,
A.A.M.C., Daniel Davis Shanahan, D.S.O.

Lieut.-Colonels: Clarence Isidore Ellis, Charles Tilson
Hudson, I.M.S.

Temporary Lieut.-Colonels: Leonard Stanley Dudgeon,
Ernest Henry Starling, F.R.S.

Temporary honorary Lieut.-Colonel Nathan Raw.

For Services Rendered in Connection with the War.

K.C.B. (MILITARY DIVISION).

Surgeon-General Sir David Bruce, C.B., F.R.S.

C.B. (MILITARY DIVISION).

Surgeon-General Francis John Jencken.

Colonels: William Coates, C.B. (Civil), Frederick Gault Finley,
C.A.M.S.

Temporary Colonel (Lieut.-Colonel R.A.M.C.T.F.) Howard
Henry Tooth, C.M.G.

Temporary Lieut.-Colonel Andrew Balfour, C.M.G.

Temporary honorary Lieut.-Colonel George Seaton Buchanan.
Major and Brevet Lieut.-Colonel Robert Markham Carter,
I.M.S.

K.C.M.G.

Colonel and honorary Surgeon-General Michael William
Russell, C.B.

Temporary Colonels: Charles Alfred Ballance, C.B., M.V.O.,
Archibald Edward Garrod, C.M.G., F.R.S.

C.M.G.

Colonels: Kenneth Cameron, C.A.M.C., Joseph Griffiths,
Charles Henderson Melville, Charles Pye Oliver, K.H.P.,
George Septimus Rennie, C.A.M.C., Wallace Arthur Scott,
C.A.M.C., Walter Langmuir Watt, C.A.M.C.

Temporary honorary Colonel Sir John Collicie.

Lieut.-Colonel (honorary Surgeon-Colonel, temporary Colonel)
William Mitchell Roodcroft.

Lieut.-Colonels (temporary Colonels): Kenneth Smith,
A.A.M.C., Douglas Murray McWhae, A.A.M.C.

Lieut.-Colonels: Henry Stewart Anderson, Louis Edward
Barnett, N.Z.M.C., John Gordon, A.A.M.C., Arthur deCourcy
Scanlan.

Honorary Lieut.-Colonel James Anderson Murdoch, A.A.M.C.

Temporary Lieut.-Colonels: James Hurley, A.A.M.C., John
Charles Grant Ledingham, George Basil Price, Charles Morley
Wemyss.

Temporary honorary Lieut.-Colonels: Harry Richard Ken-
wood, John Robertson.

Major (temporary Lieut.-Colonel) Thomas Mill, N.Z.M.C.

Major (acting Lieut.-Colonel) John Andrew Amyot, C.A.M.C.

Major Thomas Wardrop Griffith.

KNIGHT BACHELOR.

Major Andrew Macphail, C.A.M.C., Professor of History of
Medicine, McGill University, Montreal.

C.I.E.

Lieut.-Colonel and Brevet Colonel Henry Francis Cleveland,
V.H.S., I.M.S., Deputy Director-General, I.M.S.

Lieut.-Colonel Bawa Jiwan Singh, I.M.S., Inspector-General
of Prisons, Bihar and Orissa.

Lieut.-Colonel Wm. Bryan Lane, I.M.S., Inspector-General of
Prisons, Central Provinces.

Lieut.-Colonel Henry Smith, I.M.S., Civil Surgeon, Amritsar,
Punjab.

Major Henry Coddington Brown, I.M.S., Assistant Director,
Central Research Institute, Kasauli.

Assistant Surgeon Kellar Nath Das, Professor of Midwifery,
Campbell Medical School, Calcutta.

PROMOTIONS.

The following officers have been promoted to the rank
indicated for distinguished service in the field:

To be Brevet Colonels.

Lieut.-Colonels (temporary Colonels): H. E. M. Douglas, V.C.,
C.M.G., D.S.O., J. Poe, D.S.O.

To be Brevet Lieut.-Colonels.

Majors (temporary Lieut.-Colonels): A. McMunn, S. L.
Pallant, D.S.O., M. G. Winder, D.S.O.

Majors (acting Lieut.-Colonels): B. R. Dennis, G. W. G.
Hughes, D.S.O.

Majors: R. T. Brown, D.S.O., J. T. Johnson, D.S.O.,
R. McCarrison, I.M.S.

To be Brevet Majors.

Captain (temporary Lieut.-Colonel) R. E. Kelly.

Captains (acting Lieut.-Colonels): G. H. Dive, D.S.O., P. S.
Tomlinson.

Captain (temporary Major) K. W. Monsarrat.

Captains: R. C. Dun, G. W. Ellis, W. R. Galwey, M.C., A. D.
Griffith, A. S. N. Macgregor, G. Patton.

Temporary Captains: N. Duggan, H. F. Marris.

The following officers have been promoted to the rank in-
dicated for valuable services rendered in connexion with the
war:—

To be Brevet Colonel.

Lieut.-Colonel R. J. C. Cottell, T. W. O'H. Hamilton, C.M.G.,
P. H. Johnston, C.M.G., G. W. M. Moullin, J. J. Pratt, I.M.S.,
S. J. Thomson, C.I.E., I.M.S., T. B. A. Tuckey.

Major and Brevet Lieut.-Colonel J. S. Postock.

To be Brevet Lieut.-Colonel.

Major (acting Lieut.-Colonel) J. C. Furness.

Major (local Lieut.-Colonel) A. Wright.

Surgeon-Major F. P. MacCabe, Irish Horse.

Majors: W. E. A. Armstrong, I.M.S., T. W. Griffith, H. Jones,
F. W. Mott, F.R.S., H. J. Parry, D.S.O., C. G. Spencer, W. K.
Steele.

To be Brevet Major.

Captain (temporary Lieut.-Colonel) H. J. Stiles.

Captain (temporary Major) E. W. H. Groves.

Captain H. G. Gibson.

To be honorary Lieut.-Colonel.

Quartermasters and honorary Majors: A. Bruce, D. J.
Gillman, H. G. Hasell.

DISTINGUISHED SERVICE ORDER.

Bar to the Distinguished Service Order.

Major (temporary Lieut.-Colonel) Wm. M. Bell Sparkes,
D.S.O.

Captain (acting Lieut.-Colonel) Frank Worthington, D.S.O.

Temporary Captain (acting Lieut.-Colonel) James R. C.
Greenlees, D.S.O.

Distinguished Service Order.

Lieut.-Colonels (temporary Colonels): Harold P. W. Barrow,
C.M.G., Henry W. Grattan, Harry A. Hinge, C.M.G., John
W. H. Houghton, George A. Moore, C.M.G., Charles A. Peters,
C.A.M.C., Frederick S. Penny, C.M.G., Edward W. Slayter,
C.M.G.

Lieut.-Colonels: James J. Black, A.A.M.C., Samuel R.
Burston, A.A.M.C., Edward W. W. Cochrane, James E. Davey,
C.A.M.C., Charles H. Dickson, C.A.M.C., Michael H. Downey,
A.A.M.C., Thomas R. Elliott, Archibald N. Fleming, I.M.S.,
Thomas Fraser, Arthur H. Moseley, A.A.M.C., Thomas J. F.
Murphy, C.A.M.C., Henry S. Newland, A.A.M.C., Charles T. H.
Newton, N.Z.M.C., Edgar E. Powell, R.A.M.C., J. M. Y.
Stewart, A.A.M.C., Alexander H. Thwaites, A.A.M.S., Arthur
B. Ward, S.A.M.C., Arthur O. B. Wroughton.

Temporary Lieut.-Colonels: John Edward H. Davies,
Thomas McC. Leask, C.A.M.C., Wm. R. Matthews, Charles E.
Wassell, A.A.M.C.

Majors (temporary Lieutenant-Colonels): P. S. Clarke,
S.A.M.C., Reginald T. Collins, John P. Crombie, Norman E.
Dunkerton, George J. Houghton, Rochford N. Hunt, Thomas
Kay, Gerard A. Kempthorne, Sydney M. W. Meadows, Clifford
H. Reason, C.A.M.C., Henry F. Sbea, Frederick Whalley,
Charles R. White, James Wood.

Majors (acting Lieut.-Colonels): Alfred T. Bazin, C.A.M.C.,
Percy G. Bell, C.A.M.C., Richard Coffey, David L. Fisher,
James J. Fraser, C.A.M.C., John M. Gover, Alexander Leggat,
Wm. McCall, Thomas B. Moriarty, Wentworth F. Tyndale
C.M.G., Joseph Ward, James H. R. Winder.

Majors: Alan S. D. Barton, A.A.M.C., David D. Cade,
A.A.M.C., Frederick Cameron, N.Z.M.C., Clement L. Chap-
man, A.A.M.C., Walter T. Finlayson, I.M.S., Roy S. McGregor,
A.A.M.C., Edward H. Milner Moore, George S. Mothersill,
C.A.M.C., John J. Power, A.A.M.C., C. John Tozer, A.A.M.C.,
David M. Tomory, S.A.M.C., Ernest B. Waggett, George W. W.
Ware, Henry James Williams, A.A.M.C.

Captains (temporary Lieut.-Colonels): Francis L. Brandish,
Arthur T. Falwasser, William I. Thompson.

Captains (acting Lieut.-Colonels): Edmund Alderson Frederick
H. Bradley, Charles S. Brebner, Wm. Egan, Thomas S. Eves,
Wm. R. Gardner, Harold Gibson, Arthur H. Habgood, Edward
J. Kavanagh, M.C., John Dn P. Langrishe, John A. Manifold,
Ernest C. Phelan, M.C., Alexander M. Pollard, John W. L.
Scott, George P. Taylor, M.C., Wm. Tyrrell, M.C., Andrew R.
Wright.

Captain (temporary Major) Arthur W. Falconer.

Captains: Thomas Carnwath, Thomas S. Dunn, E.A.M.S.,
Harold A. T. Fairbank, Eric G. Gauntlett, Alexander J.
Gibson, John G. Gill, M.C., Alfred G. Hebblethwaite, Basil
Hughes, Stanley D. Largo, M.C., Wm. McK. H. McNallagh,
M.C., John Wm. McNee, George W. Miller, George S. Parkin-
son, Alexander D. Stirling, James H. Thomas.

Temporary Captain (acting Lieut.-Colonel) Christopher F.
Bulstrode.

Temporary Captains: John Anderson, Gordon A. McLarty,
Hugh B. Owen, Uganda Medical Service, John F. G. Richards,
Adrian Stokes.

(To be continued.)

The Albert medal has been conferred upon Captain O. R. Hoskyn, R.A.M.C., for the following heroic deed:

In France, on November 24th, 1916, as a result of a serious railway accident, a man was plucked down by the legs under some heavy girders. The wreckage was on fire, and the flames had already reached the man's ankles. Captain Hoskyn crawled into a cavity in the flaming wreckage, and, after releasing one of the man's legs, amputated the other, whereupon the man was drawn out alive. Captain Hoskyn retaining hold of the main artery until a tourniquet could be put on.

MENTIONED IN DISPATCHES.

SUPPLEMENTS to the *London Gazette* issued on December 24th and 28th, 1917, contain, in addition to the names published in our issue of December 15th, 1917, p. 806, a further list of officers of the A.M.S., R.A.M.C., Dominion Medical Corps, and the United States Army Medical Corps, mentioned by Sir Douglas Haig in his dispatch dated November 7th, 1917, for distinguished and gallant services and devotion to duty.

HEADQUARTERS STAFF.

Surgeon-Generals: Sir A. T. Sloggett, K.C.B., K.C.M.G., K.I.I.S., W. G. Macpherson, C.B., C.M.G., M. W. O'Keefe, C.B., R. Porter, C.B., R. H. S. Sawyer, C.M.G.

Colonels (temporary Surgeon-Generals): C. H. Burtchall, C.B., C.M.G., J. M. Irwin, C.B., B. M. Skinner, C.M.G., M.V.O., H. N. Thompson, C.M.G., D.S.O.

Colonels: de B. Birch, C.B., V.D., E. G. Browne, C.B., G. Cree, C.B., C.M.G., R. H. Firth, P. C. H. Gordon, S. Hickson, C.B., A. J. Luther, S. Macdonald, C.M.G., R. L. R. Macleod, C.B., S. G. Moores, C.B., F. R. Newland, C.M.G., J. M. F. Shine, W. T. Swan, C.B., H. C. Thurston, C.M.G., J. B. Wilson, C.M.G., K. W. Wright, C.M.G., C. A. Young, C.M.G.

Brevet Colonel (temporary Colonel) T. W. Gibbard, K.H.S.

Temporary Colonel H. McI. W. Gray.

Brevet Colonel H. Ensor, D.S.O.

Lieut.-Colonels (temporary Colonels): H. P. W. Barrow, C.M.G., R. J. Blackburn, C.I.E., D.S.O., E. W. Bliss, D.S.O., A. W. N. Bowen, D.S.O., F. R. Buswell, C.M.G., T. F. Dewar, H. E. M. Douglas, V.C., D.S.O., C.M.G., H. N. Dunn, D.S.O., O. W. A. Elsnor, D.S.O., H. W. Grattan, H. A. Hinge, C.M.G., J. W. H. Houghton, T. P. Jones, C.M.G., G. A. Moore, C.M.G., G. J. A. Ormsby, D.S.O., J. Poe, D.S.O., C. E. Pollock, D.S.O., C. W. Profeit, D.S.O., H. V. Prynn, M. M. Rattray, D.S.O., D. D. Shanahan, D.S.O., A. D. Sharp, C.M.G., E. W. Slayter, C.M.G., A. G. Thompson, D.S.O., H. S. Thurston, C.B., C.M.G.

Lieut.-Colonels (acting Colonels): R. W. Clements, D.S.O., W. E. Hudleston, D.S.O.

Lieut.-Colonels: A. Chopping, C.M.G., J. S. Gallie, D.S.O., H. C. R. Hime, H. G. Martin.

Brevet Lieut.-Colonel E. Ryan, D.S.O.

Major (acting Lieut.-Colonel) W. F. Tyndale, C.M.G.

Majors W. F. McAllister-Hewlings, J. FitzG. Martin, C.M.G., C. G. Thomson, D.S.O., L. V. Thurston, D.S.O., A. C. Turner, G. W. W. Ware.

Captains: T. H. Balfour, M.C., W. S. S. Berry, G. O. Chambers, A. J. Clark, M.C., G. W. Ellis, A. J. Gibson, J. G. Gill, S. S. Greaves, M.C., A. G. Hebblethwaite, A. H. Heslop, D.S.O., S. D. Large, M.C., D. C. Macdonald, G. S. Parkinson, G. W. Smith, R. E. Todd, A. Wilson, M.C., A. R. Wright.

Temporary Captains: W. H. Alderton, G. D. Hindley, K. W. Mackenzie.

Lieutenant (temporary Captain) C. W. Treherne.

Consultants.

Surgeon-Generals: Sir A. A. Bowlby, K.C.M.G., K.C.V.O., Sir G. H. Makins, K.C.M.G.

Colonels: A. Fullerton, C.M.G., Sir W. P. Herringham, C.B., W. Pasteur, S. M. Smith, A. B. Soltan, C.M.G., C. G. Watson, C.M.G.

Lieut.-Colonel C. S. Myers.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonels: T. R. Elliott, C. I. Ellis, T. Fraser, H. A. L. Howell, J. G. Jameson, W. R. Matthews, A. H. Morris, A. O. B. Wroughton.

Temporary Lieut.-Colonels: C. J. Trimble, C.M.G., V.D., J. E. H. Davies.

Temporary honorary Lieut.-Colonel N. Raw.

Acting Lieut.-Colonel C. S. Brember.

Majors (temporary Lieut.-Colonels): W. Bennett, D.S.O., E. B. Bird, D.S.O., R. Coffey, R. T. Collins, J. F. Crombie, N. E. Dunkerton, R. F. M. Fawcett, D.S.O., P. J. Hanafin, D.S.O., W. J. S. Harvey, D.S.O., G. J. Houghton, G. W. G. Hughes, D.S.O., R. N. Hunt, A. E. S. Irvine, T. Kay, H. B. Kelly, D.S.O., G. A. Kempthorne, S. M. W. Meadows, A. C. Osburn, D.S.O., W. F. Roe, D.S.O., W. M. B. Sparkes, D.S.O., F. Whalley, J. H. R. Winder, M. G. Winder, D.S.O., J. Wood.

Majors (acting Lieut.-Colonels): P. R. Ash, B. R. Dennis, A. D. Ducat, H. Fulton, J. M. Gover, F. W. Johnson, E. F. Q. L'Estrange, W. McCall, E. C. Montgomery-Smith, D.S.O., T. B. Moriarty, J. Nightingale, H. F. Shea.

Majors: W. J. P. Adye-Curran, T. A. Barron, G. A. Benson, H. D'A. Blumberg, T. D., T. S. Coates, A. W. A. Irwin, G. W. Miller, E. H. M. Moore, J. S. Y. Rogers, D.S.O., M. Sinclair, J. W. West.

Temporary Major (acting Lieut.-Colonel) E. Alderson.

Temporary honorary Majors: C. W. M. Hope, T. Houston.

Brevet Major H. F. Pantou, D.S.O., M.C.

Captains (temporary Lieut.-Colonels): J. Barkley, W. J. E. Bell, D.S.O., J. D. Bowie, D.S.O., F. H. Bradley, A. T.

Falwasser, W. R. Gardner, E. J. Kavanagh, M.C., J. de P. Langrishe, A. M. Pollard, J. Robertson, N. C. Rutherford, D.S.O., S. M. Smith, G. P. Taylor, M.C., W. I. Thompson, W. Tyrrell, M.C.

Captains (acting Lieut.-Colonels): F. L. Bradish, H. N. Burroughes, H. G. W. Dawson, G. H. Dive, D.S.O., W. Egan, T. S. Eves, H. Gibson, A. H. Habgood (S.R.), A. Irvine-Portescue, E. C. Phelan, M.C., H. C. D. Rankin, R. T. C. Robertson (S.R.), J. W. L. Scott, F. Worthington, D.S.O.

Captain (temporary Major, acting Lieut.-Colonel) T. A. Green.

Captains (temporary Majors): J. D. Fiddes, A. C. F. Turner, D.S.O.

Captains: J. G. Anderson, S. R. Armstrong (S.R.), R. P. Ballard (S.R.), J. H. Bayley, M.C. (S.R.), A. J. Beveridge (S.R.), T. R. H. Blake, M.C., R. A. Broderick, A. S. Bruzand, D. Buchanan, F. D. Caddell, M.C., W. K. Campbell, D.S.O., F. C. Chandler, P. J. Chissell, T. C. Clarke, J. Dale, R. M. Davies, A. H. T. Davis, W. H. Davison, J. W. Dew, C. K. G. Dick, R. C. Dun, J. Dundas, A. H. Falkner, J. McK. Ferguson, H. J. B. Fry, C. E. H. Gater (S.R.), R. E. Gibson, H. Goodman, H. B. Graham, A. H. Greg, T. W. Hancock, A. J. Hawes, W. S. Haydock (S.R.), J. H. Hebb, H. Henry, W. Hunt, M.C. (S.R.), A. H. Haycke, R. Jacobs, A. E. Jury, C. M. Kennedy, R. Kennon, G. D. Laing, J. H. Lloyd, P. MacCullum (S.R.), S. McCausland, W. McK. H. McCullagh, M.C. (S.R.), J. P. McGreehin, J. W. McNee (S.R.), D. G. McKrae, J. S. Manford, H. F. Marriss, S. S. Meighan, A. D. Moffat, F. R. H. Mollan (S.R.), H. S. Moore (S.R.), C. B. Moss-Blundell, J. C. Newman, C. Nicholson (S.R.), H. S. Palmer, A. C. Pearson, G. E. Pepper (S.R.), J. Pinder, G. S. Pirie (killed), J. M. Plews, R. B. Price, W. Raffle, J. Rafter (S.R.), R. T. Raine, J. Ramsay, J. F. G. Richards, F. A. Roper, P. J. Ryan, J. C. Sale, D.S.O., M.C., H. A. Sandiford, J. J. M. Shaw (S.R.), C. N. Smith, W. Sneddon, J. C. Sproule, J. Stephenson (S.R.), A. D. Stirling, E. S. Stork, D.S.O., F. Sykes (S.R.), J. H. Thomas, J. Walker (S.R.), D. L. Wall, W. S. Wallace (M.C.), G. D. Watkins, D.S.O., F. H. C. Watson, F. W. White, J. B. Williamson (S.R.), W. F. Wood, D.S.O. (S.R.).

Temporary Captain (temporary Lieut.-Colonel) H. Faulkner.

Temporary Captains (acting Lieut.-Colonels): C. D. Pyc-Smith, D.S.O., M.C., J. R. C. Greenlees, D.S.O.

Temporary Captains: E. A. Aldridge, J. Alexander, R. C. Alexander, F. H. Allfrey, J. Anderson, L. Anderson, D.S.O., G. W. Armstrong, D.S.O., W. H. Attlee, G. T. Baker, J. H. Banks, J. H. Barry, D.S.O., M.C., N. Mc. C. Boyce, E. Boyers, R. Charles, G. S. Clancy, A. Climie, J. M. Campbell, C. D. Coyle, P. W. Craig, G. McI. Dale, A. W. Dennis, C. F. Drew, J. C. Dunn, D.S.O., M.C., I. Feldman, J. H. Fletcher, D.S.O., M.C., A. Fraser, J. Gibson, W. B. Gordon, E. H. Griffin, D.S.O., M.C., E. L. M. Hackett, A. E. Halliwell, A. G. P. Hardwick, R. Herdman, W. J. Hirst, R. McC. Hill, D.S.O., R. D. Laurie, D. Lees, D.S.O., O. C. Link, J. W. Linnell, T. L. Llewellyn, H. L. McCormick, A. L. McCreery, F. C. Macdonald, A. Macintyre, D. MacIntyre, E. C. Mackay, W. Mackenzie, G. A. McLarty, G. D. McLean, I. C. Maclean, D.S.O., M.C., W. R. P. McNeight, J. C. Mackwood, J. Manuel, H. W. Moir, H. Mortimer, J. M. Moyes, H. G. Oliver, M.C., J. B. Orr, D.S.O., M.C., J. I. O'Sullivan, H. A. Pallant, D.S.O., M.C., H. Y. Riddell, R. C. Robertson, R. S. Ross, G. W. R. Rudkin, M. P. Scanlon, H. L. Shelton, S. J. Simpson, V. F. Soothill, T. Stansfield, J. L. Stewart, M.C., A. Stokes, D. J. Stokes, H. S. Sugars, D.S.O., M.C., R. I. Sullivan, J. Tate, J. N. L. Thoseby, G. G. Timpson, H. S. Turner, M.C., V. C. W. Vickers, C. D. Walker, J. Walker, K. M. Walker, F. E. S. Willis, A. Wilson, F. B. Winfield, P. R. Woodhouse, C. S. E. Wright.

Temporary honorary Captains: E. H. Hicks, C. McNeil.

Lieutenants (temporary Captains): J. H. Boag, J. La F. Lauder, D.S.O., M.C.

Temporary Lieutenants: D. H. Collingham, W. J. Isbister, H. S. Johnston, D. A. H. Moses.

Quartermaster and honorary Major J. Dunn.

Quartermaster and honorary Captain W. Wilson.

Quartermasters and honorary Lieutenants: C. W. Atkins, E. Bireb (honorary Major), J. E. Wright, J. Forman, W. Gough.

Temporary Quartermasters and honorary Lieutenants: E. C. Bowen, M. W. Colahan, G. F. Drayson, G. Foster, T. H. Griggs, R. L. Masters, H. G. Miller, T. Newling, W. Parnell, J. H. Turner.

UNITED STATES ARMY MEDICAL CORPS.

Lieut.-Colonels: H. Cabot, C. C. Collins, M. De Lancy, J. D. Fife, H. L. Gilchrist, R. U. Patterson.

Majors: G. W. Crile, H. Cushing, L. L. Hopwood, V. H. Kazanjian.

FRIENDS' AMBULANCE UNIT.

Dr. H. Nockolds.

AUSTRALIAN IMPERIAL FORCE.

Staff.

Colonels: G. W. Barber, D.S.O., A.A.M.C.; W. W. Hearne, D.S.O., A.A.M.C. (killed); R. B. Ilustable, D.S.O., V.D., A.A.M.C.; A. Sutton, C.M.G., A.A.M.C.; A. T. White, V.D., A.A.M.C.

Majors (temporary Lieut.-Colonels): J. H. Anderson, A.A.M.C.; R. S. McGregor, A.A.M.C.

Majors: H. K. Fry, D.S.O., A.A.M.C.; W. Vickers, A.A.M.C.

Army Medical Corps.

Lieut.-Colonels (temporary Colonels): J. A. Dick, M. H. Downey, A. E. Shepherd.

Lieut.-Colonels: J. J. Black, S. R. Burston, A. G. Butler, D.S.O.; H. H. B. Follett, F. A. Maguire, A. H. Moseley, H. S.

Newland, J. S. Purdy, D.S.O., J. M. Y. Stewart, V.D., C. E. Wassell, J. R. Webb.

Honorary Lieut.-Colonel E. W. Hayward.

Major (temporary Lieut.-Colonel) H. V. P. Conrick, D.S.O.

Majors: S. V. Appleyard, D.S.O., A. S. D. Barton, F. L. Bignell, L. W. Bond, D.S.O., H. P. Brownell, D.S.O., D. D. Cade, C. L. Chapman, W. B. Craig, D.S.O., W. M. A. Fletcher, A. C. Fraser, R. I. Furber, D.S.O., W. A. Hailes, D.S.O., E. L. Hutchinson, D.S.O., W. W. S. Johnston, D.S.O., M. C. H. B. Lee, D.S.O., M. C., R. M. McMaster, D.S.O., R. B. North, J. J. Power, G. S. Robinson, M.C., C. J. Tozer, H. J. Williams.

Captains: H. F. Dunstan, G. S. Elliott (killed), F. W. Fay, L. J. Hunter, J. T. Jones, M.C., I. B. Jose, A. Jnett, C. F. Robinson, J. R. Tillett (died of wounds), E. D. Watson, A.A.D.C.

Quartermaster and honorary Major T. F. Hall.

Quartermaster and honorary Captain J. I. Anderson.

CANADIAN FORCES.

Staff.

Colonel A. E. Ross, C.M.G., C.A.M.C.

Lieut.-Colonels (temporary Colonels): H. M. Jacques, C.A.M.C., D.S.O., C. A. Peters, C.A.M.C., R. P. Wright, D.S.O., C.A.M.C.

Major (temporary Colonel): A. E. Snell, D.S.O., C.A.M.C.

Canadian Army Medical Corps.

Lieut.-Colonels: R. J. Blanchard, J. E. Davey, C. H. Dickson, J. A. Gunn, J. Hayes, T. J. F. Murphy, F. W. E. Wilson.

Majors (temporary Lieut.-Colonels): A. T. Bazin, J. N. Gunn, T. McC. Leask, C. H. Reason.

Majors (acting Lieut.-Colonels): P. G. Bell, J. J. Fraser.

Majors: D. J. Cochran, G. S. Mothersill, S. Paulin.

Captains: L. E. Clark, W. J. E. Mingie.

Lieutenant W. McL. Moore (Canadian Red Cross).

Quartermaster and honorary Captain J. E. Tulloch.

NEW ZEALAND FORCE.

Staff.

Colonel C. M. Begg, C.M.G., N.Z.M.C.

Medical Corps.

Colonel D. J. McGavin, D.S.O.

Lieut.-Colonels: D. N. W. Murray, D.S.O., J. H. Neil

Majors: F. G. Cameron, K. MacCormick, D.S.O., R. H. Walton.

Captains: H. M. Goldstein, M.C., I. N. Spedding.

SOUTH AFRICA.

Medical Corps.

Lieut.-Colonel A. B. Ward, commanding South African General Hospital.

Quartermaster and honorary Lieutenant W. Richardson.

BRITISH WEST INDIES REGIMENT.

Temporary Surgeon Captain W. S. Mitchell.

INDIAN ARMY.

Indian Medical Service.

Lieut.-Colonel A. N. Fleming, Major J. J. Urwin.

The list also contains a number of names of N.C.O.'s and men of the R.A.M.C., A.A.M.C., C.A.M.C., N.Z.M.C., S.A.M.C., and members of the various nursing services.

THE name of temporary Captain Frederick Edward Saxby Willis, R.A.M.C., attached Seaforth Highlanders, was accidentally omitted from the list of recipients of the Military Cross published in our issue of December 22nd, 1917, p. 839.

NEW YEAR HONOURS.

THE following New Year Honours have been conferred upon medical men, in addition to those specifically awarded for services in the field and in connexion with the war, published at pp. 30-32. On behalf of the medical profession we offer congratulations to all those of our number whose distinguished services have thus been recognized:

G.C.V.O.

Sir Bertrand Dawson, K.C.V.O., C.B., M.D., Physician in Ordinary to H.M. The King, Physician London Hospital.

K.C.V.O.

Lieut.-Colonel Hugh Mallinson Rigby, R.A.M.C., F.R.C.S., Surgeon to H.M. The King's Household and to H.M. Queen Alexandra's Household, Surgeon London Hospital.

M.V.O.

Staff Surgeon Louis Greig, R.N., M.B., Ch.B.

K.C.B.

Sir George Newman, M.D., Principal Medical Officer to the Board of Education.

KNIGHTHOOD.

Dr. Barclay J. Baron, Consulting Physician for Diseases of the Throat and Nose, Bristol General Hospital; ex-President of the Bath and Bristol Branch of the British Medical Association.

Dr. Thomas J. Horder, Assistant Physician St. Bartholomew's Hospital.

Dr. John Phillips, Emeritus Professor of Obstetric Medicine, King's College; Consulting Obstetric Physician, King's College Hospital.

Mr. Harold J. Stiles, M.B., C.M., F.R.C.S. Edin., Surgeon Royal Edinburgh Hospital for Sick Children.

KAISAR-I-HIND GOLD MEDAL.

Dr. Ernest Neve, Surgeon Mission Hospital, Srinagar, Kashmir.

Scotland.

THE PROPOSED MINISTRY OF HEALTH.

THE Royal College of Physicians of Edinburgh has issued a statement dealing with the question of the establishment of a Ministry of Health. Under the privileges conferred by its charter it is the duty of the College to consider "any matters affecting the general interests of the medical profession and the public." The College has accordingly considered this question, and has accepted the general proposition that it would be to the advantage of the public health were the various existing health agencies co-ordinated and brought under the supervision, control, and initiative of a board of health, constituted on the lines suggested in the statement, and presided over by a Minister of State. The only aspect of the question which leads to a divergence of view is as to the desirability of proceeding with a scheme of such magnitude at this strenuous and anxious time in the nation's history, when the medical forces of the country are large disorganized. In the circumstances the prevailing opinion of the College is that the establishment of a Ministry of Health ought to be postponed until after the war.

Statement by the Royal College of Physicians of Edinburgh.

The Royal College of Physicians of Edinburgh was erected by Royal Charter granted by His Majesty King Charles the Second, 29th November, 1681, and incorporated anew by Royal Charter granted by Her Majesty Queen Victoria, 16th August, 1861. The Royal College has been, and continues to be, largely concerned with matters affecting the health of the nation. It has taken considerable part in developing medical science and practice. It is therefore particularly interested in all proposals which have for their aim the erection of a State Department of Health. The Fellows of the College have given careful consideration to the subject. The statement which follows is the outcome of deliberations which had regard to the great questions of health and the urgent need of their recognition and effective handling by the State. The standpoint of the College is frankly medical, not political or departmental.

The administration of health measures has in the past been developed in connexion with a number of Government Departments, such as the Local Government Board, Home Office, Board of Education, Insurance Commission. Each of the several departments has worked within the limits of certain Acts of the Legislature dealing with definite subjects and conferring definite powers. The health of the community has received benefit from the work of the departments; but the operations of the departments have not attained that comprehensive measure of success which the extent and gravity of the health problem demand.

As regards health questions, the sphere of the several departments is limited, and, with increasing legislation, the overlapping which inevitably follows from their separation becomes steadily aggravated. A fundamental weakness lies in the fact that in none of the departments concerned is the control vested in a minister appointed primarily to deal with health problems.

From this division of interest and responsibility departmental difficulties are apt to arise; policy in regard to matters pertaining to health tends to become subject to considerations of departmental jurisdiction; and the essential interest of health questions is liable to be obscured. Under the restrictions of the present system it has been impossible to evolve concerted means for dealing with the complex and ever widening problems of national health. Not until these restrictions are removed will it be possible to attain effective and adequate machinery.

What is required is the creation of a ministry which shall concern itself with health matters pure and simple, and to whose jurisdiction shall be transferred from other departments the operations of all existing enactments in so far as they deal with health. This opens up another aspect of the question, namely, the immense extent of the issues involved. Existing Acts deal only with sections and fragments of the subject. A multitude of conditions affecting health are not included in the purview of the Acts, and have hitherto been left untouched.

The Minister of Health must handle the whole problem. He must be concerned not only with questions already dealt with by the Legislature, such as infectious diseases, infant welfare,

etc., but also with fresh questions arising from time to time, for example, conditions causing or affecting forms of sickness and disease not yet included within the operation of Health Acts. Such matters are frequently brought to light in the work of the medical profession. Beyond the treatment of individual cases by medical practitioners there are large questions concerning conditions to which sickness is due. These are certainly matters for a Ministry of Health.

To enable the Ministry to carry out its wide and highly complex functions, a Board of Health should be constituted, and its members selected in such a way as to ensure that the attention of the Ministry of Health would be directed to all matters affecting health.

The Royal College of Physicians of Edinburgh is, therefore, of opinion that it is essential, in the public interest, that a Government department should be erected to deal exclusively with health.

The Royal College suggests:

I. That the department should consist of a Minister and a Board of Health, of which the Minister should be chairman, and whose members should be elected on the ground of experience and interest in matters pertaining to health.

II. That the purposes of the department should be: (1) To administer the Health Acts. (2) To devise executive measures for dealing with health problems not hitherto defined by legislative measures. (3) To institute inquiries with a view to introduce measures for improving conditions affecting health. (4) To develop facilities for investigation of problems in health and disease as they may arise.

III. That the Board should include three groups of members: (1) Administrative officials. (2) Laymen with wide experience of health problems, or in the administration of hospitals and other health agencies, official or voluntary. (3) Medical members who have had experience in: (a) public health service; (b) general practice; (c) special clinical department, including industrial medicine; (d) medical research; (e) medical statistics.

In name and by authority of the College,

WILLIAM RUSSELL, M.D.,

President.

A. DINGWALL-FORDYCE, M.D.,

Secretary.

Edinburgh, December 6th, 1917.

PRELIMINARY EXAMINATIONS AT THE UNIVERSITIES.

The report of the Joint Board of Examiners of the Scottish Universities contains statistics of the passes and failures at the medical preliminary examination. At St. Andrews 17 entered—4 failed in all subjects entered for, 9 passed in all subjects entered for, 1 passed in two subjects and 3 in one subject; at Glasgow 106 entered—39 failed in all subjects, 47 passed in all subjects, 5 in two subjects, and 15 in one subject; at Aberdeen 24 entered—2 failed in all subjects, 13 passed in all subjects, 1 in two subjects, and 8 in one subject; at Edinburgh 72 entered—19 failed in all subjects, 30 passed in all subjects, 1 in three subjects, 7 in two, and 15 in one.

SCOTTISH JUBILEE NURSES.

The annual report of the Scottish Branch of the Queen Victoria's Jubilee Institute for Nurses states that 121 were absent on military nursing service and that 10 had been mentioned in dispatches or had received war honours. Nurses were doing good work in many lonely districts of Scotland under the Highlands and Islands Medical Service Board, and also for infant welfare schemes. There are now 276 nursing associations in affiliation with the Scottish Branch. Dr. J. Haig Ferguson, in seconding the adoption of the report, said that there was no more welcome visitor from the point of view of the doctor or the patient than the Jubilee nurse, and added that all should be enrolled with the Central Midwives Board. Dr. Angus Macdonald paid a tribute to the services of the nurses from the point of view of the general practitioner.

Ireland.

PRESENTATION OF BOYLE MEDAL.

At a recent scientific meeting of the Royal Dublin Society, when Lord Rathdonnell, President, was in the chair, the Boyle Medal was presented to Professor J. A. McClelland, Sc.D., F.R.S.

The report of the committee of the honorary officers, recommending the award, adopted by the Committee of Science and the Council, stated that the claim of Professor McClelland to the medal was based upon research in many branches of science, but primarily in those which deal with ionization as resulting from additions of electrons to gaseous molecules, or aggregates of such, and with the more recently discovered forms of radiation associated

pre-eminently with radio-activity. His work on ionization had been used by Sir J. J. Thomson in his work on conductivity through gases, and his discoveries in secondary radiations had been the starting point of much similar work in England and abroad. More recently Professor McClelland had served with distinction on the Advisory Council instituted by the State. The occasion was the sixth on which the medal had been presented. Professor J. Joly, F.R.S., enlarged on some points in Professor McClelland's papers, and Professor H. Conway, F.R.S., added a tribute to the industry of the medallist.

The President presented the medal with a few well-chosen words, expressing the goodwill of all sections of the society, and Professor McClelland, having acknowledged the honour, remarked that the future for research work was becoming very bright, for the industrial combinations to further research would lessen the difficulty experienced by those who devoted themselves to it in finding no openings afterwards.

VACCINATION DEFAULTERS.

The Local Government Board has pointed out to the guardians that the number of vaccination defaulters in Wexford Union has increased to 3,306, and has urged them to continue prosecutions until the whole list is exhausted. The clerk announced that it had been decided to prosecute in fifty-six cases.

An additional war bonus of £7 a year each has recently been granted by the Derry Guardians to the eight maternity nurses in the union.

England and Wales.

LONDON ASSOCIATION OF MEDICAL WOMEN.

At a meeting of the London Association of Medical Women on December 11th, with Lady Barrett in the chair, a discussion took place on (a) the advisability of a special department for maternity and child welfare under a Ministry of Health, and (b) the merits of municipal as opposed to voluntary control in maternity and child welfare. Miss Harris, of the Women's Co-operative Guild, said the subject was of special importance now, on account of the many new occupations open to women, which might seriously affect their health in pregnancy, whereas after the war there would probably be limited employment and shortage of food. There were two main difficulties to be met: (1) bad environment, and (2) poverty, standing in the way of proper medical attention and nursing. National and municipal action was essential, individual efforts being inadequate. The two great national agencies concerned with the health of the people were national health insurance and the public health authorities. The former allowed (a) maternity benefit of 30s. to insured women and wives of insured men, but it left paupers out of account, and in any case the amount was insufficient. (b) Payment of sickness benefit to insured married women; this was unsuitable, as the test was incapacity to work and the allowance was only made after three days' illness, while the proposal to convert maternity benefit into a marriage dowry was unsound. The Local Government Board issued valuable reports and paid 50 per cent. of the cost of infant welfare centres established by local authorities. But the distribution, remuneration, and training of midwives needed much revision. There was a shortage of maternity hospitals and homes; dinners and milk should be provided for expectant and nursing mothers, and there should be a supply of home helps. A Ministry of Health should have a strong maternity department, largely staffed by women. Mrs. Hood said that the women of the Co-operative Guild were looked upon as the thrifty working class. They disliked charity and felt that during the period of maternity they had a right to care and attention, just as their children had a right to free education. Municipal was preferable to voluntary control and savoured less of charity. Antenatal centres were much appreciated by the working classes and maternity hospitals were essential. Dr. Christine Murrell thought the endowment of motherhood might solve the question. She advocated the union of municipal and voluntary control in maternity and child welfare work; the municipal

body would then find the funds and the voluntary factor would supply the initiative, while the scheme would not be hampered by cumbersome machinery. Dr. Janet Lane-Claydon said that maternity hospitals were very few in the provinces, but adequate in London, provided the beds were used for abnormal cases only. She thought there would be great difficulty in safeguarding the home during the mother's absence. She was strongly in favour of a combined male and female staff at the head of a maternity department under the Ministry of Health. Lady Barrett said that the provision of beds for pregnancy sickness was inadequate even in London. It was obvious that voluntary initiative had been largely responsible for the public interest in the work, but it seemed impossible to make the work uniform and complete without some central controlling body which should supply the funds. There was no reason, however, why municipal authorities should not very largely make use of the voluntary help already being given.

THE LIVERPOOL MEDICAL INSTITUTION.

The first pathological meeting of the Liverpool Medical Institution was held on December 20th, 1917, Dr. Macalister, the President, in the chair. Several specimens, macroscopic and microscopic, were shown, of which the following were of special interest: Rapidly growing sarcoma following injury with secondary deposits in the liver, sarcoma of the stomach, aneurysm of the heart rupturing into the pericardium, endothelioma of the finger, and granular kidney with cerebral hæmorrhage in a boy aged 15. Mr. Thurstan Holland exhibited skiagrams of two cases of congenital deformity of the bones of the hands and feet, showing fusion of some of the bones of the tarsus and metatarsus, as well as of the carpus and metacarpus. The patients complained of little or no discomfort, and such a condition could not have been diagnosed in the absence of x rays. Apparently very few cases of this deformity are on record, and they were only discovered through the patients complaining of never being able to move the extremities quite as freely as desirable. Captain Cone, M.O.R.C., U.S.A., read an interesting paper on some pathological conditions of peripheral nerves resulting from war injuries. He illustrated his points by numerous lantern slides, and supported the view, on the strength of his observations, that in separated nerves sensibility of the structures beyond the site of lesion was maintained through a nexus established between the uninjured nerve fibrils in the skin and adipose tissue. Captain Cone was able to show the feasibility of such a connexion by microscopic slides. He was unable to show whether intramuscular nerve filaments performed a similar function. He thought that growth from nerves uninjured and situated in the skin and adipose tissue linked up with branches and fibrils from the distal ends of the severed nerve trunks.

Correspondence.

THE MINISTRY OF NATIONAL SERVICE.

SIR.—The letter of your correspondent last week raises some general questions, as, for instance, the natural history of committees, on which, were time and paper not so scarce, it might be interesting to speculate, and at least one matter of detail deserving very careful consideration. He says, somewhat cynically, of the Medical Department of the Ministry of National Service, that it is too young to be open to much criticism. I am told by those who profess to know that the medical arrangements of that department are working well in spite of not a few difficulties, among which must be reckoned the unpopularity of the military department it in part replaced. Your correspondent sees that one of its chief dangers is the magnitude of the task thrust upon it, but it is not clear that he appreciates fully how great this task may become. If it proves its usefulness, and other Ministries learn to depend upon it for information and guidance in medical matters, it may be called upon to take charge of a very much larger field in civil life, and eventually—possibly in no long time—to undertake, though not, perhaps, under the same auspices, much other work that will need to be done as a consequence of the social changes set up by the war.

As yet the profession does not speak with a single voice. The British Medical Association aspires to do so, but has never had the political wisdom to come to an understanding with the Colleges, which for their part show interest in the general affairs of the profession only spasmodically, and as it were grudgingly. Within the Association there is dissension, one section denouncing it for neglecting the interests of panel practitioners and the other decriing it because it thinks too much of them.

The Ministry of National Service has very important duties which cannot end with the war. The civilian profession is for the first time really represented in the Government, and it has such an opportunity through this representation as may serve to bring to fruition many avowed professional aims and to re-establish it on a basis sufficient to meet all impending socio-economic changes (the probabilities of which are undoubted) while resolving its present condition of transition.

The immediate need is the more wide distribution of Government medical work on a part-time basis, the ideal being that every practitioner be called upon to do an equal amount of this in addition to discharging his more general obligations to the civilian population. When the other work consequent on the incidence of the war requires to be done, the present system can, if necessary, be applied with any required modification.—I am, etc.,

January 1st.

THE TREATMENT OF TRAUMATIC PARAPLEGIA.

SIR.—The article in your issue of December 29th, 1917, upon "The treatment of paraplegia from gunshot or other injuries of the spinal cord," calls for serious criticism. Colonel Mayo-Robson asks: "If we can by operative means remedy paralysis due to nerve destruction by transplanting new nerve tissue or part of the spinal cord of one of the lower animals, as I proved possible some years ago, why should we not be able to obtain return of function in a damaged spinal cord by excising the injured section and transplanting into the gap thus made a portion of the spinal cord of a recently killed rabbit, or perhaps better, of a sheep or calf?" The cases quoted of restoration of function by grafting¹ refer to injuries of peripheral nerves, which differ in at least one essential respect even from the medullated fibres of the spinal cord, namely, in possessing a neurilemma sheath. This sheath plays a critical and apparently indispensable part in regeneration. Further, the structure and function of a peripheral nerve are infinitely less complex than those of the spinal cord.

The case against the experimental operation suggested by Colonel Mayo-Robson rests upon definite experimental facts. The whole question of the possibility of regeneration of the spinal cord, together with many references to the literature on the subject, is discussed in Schüter's *Textbook of Physiology*, 1900, p. 878. Therein it will be found that no evidence of the possibility of regeneration of the spinal cord has been found by experiments upon animals higher in the scale than *Lacerta viridis*.

The account of the two cases quoted by Colonel Mayo-Robson as encouraging the belief that regeneration might occur, is so lacking in detail as to be quite unconvincing. The danger that the proposed operation may be carried out is intensified by two facts—first, that it is suggested by a surgeon of such high standing, and secondly, that patients with recoverable, or partly recoverable, lesions, disheartened by the slowness of their progress and the apparent hopelessness of their condition, may be, as Colonel Mayo-Robson says, "willing to undergo operation even if it gives the barest possibility of success." It is true that Colonel Mayo-Robson specifies that only the hopeless cases should be thus operated upon, but the single case which he cites as having so far been submitted to operation was one of incomplete division of the cord. Further, the diagnosis between incomplete and complete lesions, more especially in the earlier weeks or even months, before the urinary tract has become irremediably infected, is still often a matter of great difficulty. At the present time there exists neither experimental nor clinical evidence that an operation of grafting upon the spinal cord does offer even the remotest possibility of

¹ BRITISH MEDICAL JOURNAL, September 15th, 1896, and October 31st, 1896.

success, and it seems cruel to hold out to these unfortunate patients any hope whatever that, by submitting to a severe operation, by no means intrinsically devoid of danger, their condition may be benefited.—I am, etc.,

London, W., Jan. 2nd.

PERCY SARGENT.

PRIMARY EXCISION OF GUNSHOT WOUNDS OF THE ELBOW-JOINT.

SIR,—I was particularly glad to see the letters you have recently published on this subject from Messrs. Mansell Moullin and Swan, because, having in the earlier stages of the war to undertake secondary excisions of some difficulty for such cases in a late stage after they had gone through the often serious septic period, I urged in a lecture delivered at Guy's in April, 1916, and subsequently published, a wider application of primary excision. Undoubtedly primary excision was at that time being practised by some surgeons both for the elbow and shoulder, and I have since had occasion to know that the utility of these operations is generally recognized at casualty clearing stations. But I do not think I am quite in agreement with Mr. Swan as to his use of the term primary, and I gather from his letter that Mr. Mansell Moullin shares my view when he urges that these operations should be undertaken, as they often are, at casualty clearing stations. As Mr. Swan very rightly points out, excision at the base gains for the patient very definite advantages, not the least of which is the "control of sepsis," but my contention would be that a primary excision undertaken at a casualty clearing station within a few hours of infliction of the wound should be one of the means by which sepsis is inhibited and the patient is spared a long septic convalescence, possibly several operations for the removal of sequestra, and the formation of a firm mass of scar tissue around the joint which makes a secondary excision a much more formidable proceeding. In all of Mr. Swan's cases quoted in the *Proceedings of the Royal Society of Medicine*, May, 1917, septic infection was already present, and I venture to think that they cannot therefore be regarded as instances of the value of "primary" excision. Those who have been working at casualty clearing stations for two or three years without opportunities of correcting or confirming their opinions and practices by the knowledge of what is the ultimate judgement on them by those working at the base exhibit a very keen and laudable spirit of inquiry as to the end results of such and many other common casualty clearing station operations, and, as I know from recent personal experience, receive suggestions or criticisms in the most friendly manner; this is only one of many subjects on which the judgement of those who have wide experience at home would be heartily appreciated by surgeons who have only casualty clearing station experience to guide them.

If it were possible to improve most of the surgery done at casualty clearing stations it would be by the wider dissemination amongst the surgical specialists working there of the end results of war surgery.

I find that I have notes of seven cases of primary excision of the shoulder or elbow carried out at the time when the wounds were as far as possible completely excised, and foreign bodies, if present, removed; the chief indication seems to have been involvement of the articular surface with comminution, and on the extent of comminution must depend the amount of bone removed. As far as I can judge, there is a greater probability of restriction of normal movement by bone reformation, particularly in the elbow, than that too free removal of bone will result in a flail joint. If the injury was limited to the bones of the forearm, the humerus was left intact, and similarly, whenever possible, the radius and ulna were spared and the cut end of the humerus allowed to rest above the greater sigmoid cavity of the ulna. As my cases were usually able to be sent to the base within twenty-four hours, I have no knowledge of the end results, and it is chiefly in the hope that I may learn something from those into whose hands they have passed—particularly if the results have been imperfect—that I am now writing.—I am, etc.,

London, W., Dec. 13th, 1917.

C. H. FAGGE.

SIR.—Major Hey Groves has, no doubt inadvertently, misrepresented what I wrote upon this subject. I have never advocated "primary excision of the elbow-joint in

the presence of virulent sepsis." On the contrary, I deprecate most strongly any attempt at such a proceeding. It can only end in disaster. It is too late then, and there is nothing for it but to wait. But if, before this stage has been reached, while the infection has not yet spread into the soft tissues beyond the possibility of excision, the whole cavity is laid open, all damaged tissue and broken fragments of bone removed, and with them so much of the ends of the bones as will secure a sufficiently firm fibrous joint, much pain and suffering can be saved, and the arm will regain its full use in a far shorter time than under the present method of conservative treatment.—I am, etc.,

London, W., Dec. 23rd, 1917.

C. MANSELL MOULLIN.

"PAINLESS CHILDBIRTH."

SIR,—The discussion of scopolamine-morphine narcosis in childbirth reported in your issue of December 15th involves questions of such national and even world-wide importance that an attempt at an elucidatory summary of the facts stated and a few comments thereon may possibly be of interest to your readers. I propose to allude to the five reports in the numerical order in which they are printed.

The reports do not state whether there was any selection of the cases; it may be presumed, however, that narcosis would not be adopted in cases already autotoxic from albuminuria, etc., and the patients were therefore in a certain measure selected.

The narcosis would seem to have been fairly equal in all, complete amnesia varying from 46.2 to 55.0 per cent.; hence the resulting phenomena might be expected to correspond very closely in the different sets of observations; this, however, is not the case; they vary very widely, and in some respects contradictorily. The details are variously summarized, making comparison difficult.

The narcosis, for example, is reported by No. 5 as being accompanied by excitement in 35 per cent., with maniacal excitement in a few. No. 4 says there was restlessness in 50 per cent., but no active delirium. The rest are silent on the subject of delirium. Again, in regard to involuntary muscular action, No. 1 reports of the first stage "there is sometimes entire cessation," the second is "markedly prolonged," and the third also prolonged. No. 2 reports "diminution in first stage for an hour or two, afterwards normal." No. 3 summarizes "marked delay in labour." No. 5 records "marked delay in labour, and on the contrary No. 4 states that labour did not seem so prolonged after the first injection; "any prolongation occurred before the injection." Of voluntary bearing down No. 1 reports "lack of, especially in primiparae"; No. 5, "as a rule subnormal, absent in 10 per cent."; No. 2, "present in 68 per cent."

Abnormal labours were reported by No. 1 as being in large proportion, Nos. 2, 3, 4 make no comment, and No. 5 remarks that there was an increased failure of occipito-posterior positions to undergo spontaneous rotation attributable to the lack of bearing-down efforts.

Instrumental relief was reported by No. 1 in 45 per cent.; is not stated in No. 2; No. 3 says was required in second stage owing to absence of strong expulsive efforts; No. 4 reports its use in 17.9 per cent. but as not being due to the effects of the drug. No. 5 reports an increase and "relatively difficult," owing to failure of bearing-down efforts. Ruptured perineum is recorded by No. 5 only, as being greatly in excess, due to difficulty in controlling the patient. Retention of urine was mentioned in one report only as occurring in 10 per cent.

The effects on the child seem to consist in very frequent difficulty in starting respiration, often with blueness and limpness, and it seems probable, as the President remarked, that the mortality was increased.

It would be of interest to compare these results with those of delivery in ordinary alcoholic narcosis; there must be ample material to make such a comparison, since a country midwife recently stated that it was customary on her arrival at a case in her district to be presented with a bottle of brandy and another of whisky, being asked to choose which she would take herself and which she would give to her patient. Since humanity is more or less tolerant of alcohol its use would probably be better borne than the drug in question and the patient would have the advantage, as in the example quoted, of enjoying her favourite form of alcoholic narcotic.

The view that narcosis prolongs labour, and that it would be still more prolonged but for instrumental interference, is largely admitted in these reports, and the acknowledged condition of the child at birth makes it probable that this might determine a fatal result in weakly or premature infants. This makes it very urgent that the registration of stillbirths should become a part of our law at the earliest possible date, with a proviso that the fact of birth under narcosis should be stated in the certificate, so that an inquest might be held if necessary.

I sincerely hope that all societies engaged in the effort to reduce infant mortality will direct their attention to this procedure, which threatens to assume very large proportions, and may still further lessen our diminishing birth-rate.—I am, etc.,

London, N.W., Dec. 22nd, 1917.

HENRY RAYNER, M.D.

COMPRESSED MOSS DRESSINGS.

SIR,—Will you permit me to draw the attention of surgeons who are using sphagnum moss in military hospitals to the compressed form of moss dressings? Owing to their small bulk there is saving of cubic space in transport, also economy in use of packing materials. They are very carefully sublimated and otherwise prepared by workers who have had some years' experience. Before use the compressed dressing has to be expanded by soaking in lotion, but this is a very simple proceeding, and full directions are sent along with the dressings.

The workshops making these dressings are capable of turning out considerably more than they are at present asked to do, and as this form of dressing may not be so well known as the other forms, samples of compressed dressings, which are made in standard sizes, will be forwarded on application to the D.G.V.O., Scotland House, New Scotland Yard, London.—I am, etc.,

CHARLES W. CATHCART,

Lieut.-Colonel R.A.M.C.(T.).

Edinburgh War Dressings Supply,
37, Palmerston Place, Edinburgh, Dec. 27th, 1917.

WAR NEPHRITIS.

SIR,—I have read with interest the articles on war nephritis by Sir Thomas Oliver, and Captains Dunn and McNee. The last-named writers state that cases of war nephritis "with copious haematuria have certain features in common." This has also been our experience. Observations have been made on sixty such cases, and the history in the great majority is so similar that one cannot think it a mere coincidence.

Regimental medical officers are familiar with trench fever. All know how often painful shins occur either with or after the attack. How often one has to send men to hospital just because of this troublesome shin pain!

In hospital these patients are frequently seen. They sit up at night rubbing their shins—sleep is difficult, often impossible. On examining the shins in well-marked cases, wasting sensory changes are found. The recovery in most is slow, in others the following may complicate matters:

(1) Systematic examination of the urine in these cases shows that the urine is turbid. Pus cells may be present, and casts of a granular nature are not infrequent.

(2) A sudden pyrexia followed by haematuria.

(3) A definite nephritis with oedema (usually slight in these cases) but always showing a tendency to another pyrexial attack with haematuria. This may follow either (1) or (2).

This sequence of events may be purely accidental or otherwise indicative. One has seen trench fever in the line—seen painful shins follow it, sent the men to hospital, and learnt afterwards that in some nephritis followed. In hospital this war nephritis (haematuric variety) supervenes in these shin cases, and amongst all the diseased conditions in a medical division one has rarely seen it follow anything else. One has come to regard the sequence as a clinical group.

The suggestion is made on clinical grounds that these cases of painful shins (neuritic) and many cases of war

nephritis (haematuric) are complications of trench fever; the suggestion is worth consideration.—I am, etc.,

December 12th, 1917.

ALEX. WM. HENDRY,
Captain R.A.M.C.

THE FOOD REQUIREMENTS OF THE SEDENTARY WORKER.

SIR,—Your estimate of the sufficiency of food is based entirely on the number of calories the food contains, and, as far as I know, every other estimate published is calculated by the same standard. I submit that this basis is insufficient, is grievously insufficient, and may be very fallacious.

In the first place, it omits altogether the necessity of vitamins. The amount of certain vitamins that is necessary for the maintenance of health has been calculated, and works out at about $2\frac{1}{2}$ grains (not grams) per day for a man of 11 st. The value in calories of these $2\frac{1}{2}$ grains is altogether neglectable, but they are of vital necessity in the diet. How then can a diet that is estimated in calories alone be pronounced sufficient? It may contain a superabundance of calories, and yet be gravely and even fatally insufficient.

Your scale was calculated for sedentary workers, but it took no account whatever of the character of the work done by the sedentary worker, and I submit that a diet scale that takes no account of the character of the work is as inefficient as one that takes no account of the quantity of the work. Different quantities of work require different diets, it is true; but different kinds of work also require different diets. At any rate, when we are calculating a minimal diet, it is surely of importance to take into account the kind of work as well as the quantity of the work.

I have shown by a demonstration admitted by you to be valid, that a certain minimum of protein is necessary to mental efficiency. Mental exertion of minimal amount utilizes and requires a certain minimum of protein. If this is so, is it not extremely likely that mental exertion beyond the minimum requires an amount of protein beyond the minimum? Is it not likely that what is true *simpliciter* is true *secundum majus et minus* also? Your calculations are made with respect to sedentary workers, as if the output of muscular exertion were all that need be taken into account; but sedentary workers may be employed on work, such as copying or typewriting, that is almost wholly automatic, and requires the minimum of mental exertion; or they may be employed in working out problems of the utmost intricacy and difficulty, involving great and prolonged mental exertion. Is it to be assumed as a matter of course that the diet scale of these two kinds of workers must be the same, and ought to be the same? Is it not almost certain that they ought to be different? I submit that when the number of calories has been estimated the task of composing a diet scale is not completed—it is only begun. Even in the matter of calories alone, is no distinction to be made between one sedentary worker and another? Is the Home Office official, who works, beside a roaring fire in a double-windowed, turkey-carpeted, tobacco-atmosphered lounge, at the problem of the number of calories he requires in his food, to be placed on the same allowance as the man who works, insufficiently clad, in a draughty shed, at some unintellectual sedentary occupation such as may fall to the lot of any of us any day—such, for instance, as picking oakum? Sir, if you will take your place, voluntarily or involuntarily, in the latter situation, I think you will feel the necessity of different diet scales for different sedentary workers.—I am, etc.,

Parkstone, Dorset, Dec. 23rd, 1917.

CHAS. MERCIER.

* * * We publish elsewhere (p. 25) a note on the points raised in this letter, and a further discussion of the general subject in a leading article on the logic of the food position.

FUND IN AID OF DR. J. F. C. MEYLER OF DUBLIN.

SIR,—In the JOURNAL of October 13th, 1917 (p. 497), you were good enough to give publicity to the appeal which was made in this case, the result of which I am pleased to say has been quite satisfactory. I shall feel obliged if you will allow me, on behalf of the Committee, to thank the

subscribers, through your valuable medium, for their prompt and generous response.

My Committee are also greatly indebted to you for your kind assistance in the matter.—I am, etc.,

TREVOR N. SMITH,

Honorary Secretary, Meyler Fund.

8, Upper Fitzwilliam Street, Dublin,
Dec. 27th 1917.

Obituary.

WILLIAM DUNCAN, M.D., F.R.C.S.ENG.,

CONSULTING OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL.

We regret to record the death, at the age of 61, of Lieut.-Colonel William Duncan, formerly obstetric physician to the Middlesex Hospital, and senior physician to the Chelsea Hospital for Women. Dr. Duncan studied medicine at St. Thomas's Hospital, where he won various scholarships and prizes. He qualified L.S.A. in 1879, obtained the M.D. degree of the University of Brussels, with first class honours, in 1880, and the diplomas of M.R.C.P.Lond. and F.R.C.S.Eng. in 1883. After holding with distinction several house appointments at St. Thomas's Hospital, and a prosectorship at the Royal College of Surgeons, for which he was awarded a first class certificate of honour, he was appointed lecturer in practical midwifery at the Middlesex Hospital, and assistant physician to the Chelsea Hospital for Women. In later years, as he rose to the senior post at each of these two institutions, he acted as examiner in midwifery and the diseases of women at the English Conjoint Board, the University of Glasgow, the Victoria University of Manchester, and the Apothecaries' Society. While resident accoucheur at St. Thomas's Hospital in the early eighties he was responsible for three annual reports of the obstetrical department of that hospital, and he subsequently made various contributions to the literature of gynaecology and obstetrics. On his retirement from active practice Dr. Duncan was appointed to the consulting staffs of the Middlesex and Chelsea Hospitals. In 1909 his zeal on behalf of the volunteer movement was rewarded with the Territorial Decoration, and during the next five years he served as lieutenant-colonel commanding the Middlesex Yeomanry. He was a justice of the peace for the County of Bucks, and in 1908 held the office of sheriff.

Mr. VICTOR BONNEY writes:

I worked with and under the late William Duncan for many years, and should like to express my esteem for him. He was a genial and kind-hearted man, and generous and loyal to his colleagues and juniors. As an operator he was exceedingly conscientious, careful, and neat, and possessed in a high degree the qualities of tenacity and determination, so that though he never adopted the full gamut of modern aseptic technique, his cases did exceptionally well at a period when the mortality and morbidity of abdominal section were much greater than at present. Had his entire energies been applied to his professional work he would have accomplished far more than he did, but his conviction (now so fully proved right) that national defence was the first concern of all men led him to devote much of his time to voluntary military service. His long-time ambition was about to be realized, and as colonel of his yeomanry regiment he was just going to France when the incurable condition from which he died suddenly declared itself. Though he knew that death in sudden agony might come to him any minute, and could not be long delayed, an invalid, and in more or less constant pain and discomfort, he maintained the same steady fortitude and courage which I shall always remember as his chief characteristic in the operating theatre.

We are indebted to Mr. COMYNS BERKELEY for a personal memoir from which we take the following extracts:

Apart from his professional attainments, which were of a high order, William Duncan will be remembered most for his unswerving loyalty to his friends, and for the thoroughness with which he did everything that he took up. A St. Thomas's man, from the day he was appointed

to the staff of the Middlesex Hospital until the day of his death he was imbued with the spirit of Middlesex, and, while in its active service, he in every way identified himself so much with this institution that it may truly be said it never had a more devoted member. A large number of residents and students have had occasion to be grateful for the help he gave them.

Everything that Duncan seriously took up he did well at. In his early days he joined the Duke of Cambridge's Hussars as surgeon, but as this post gave him very little to do he changed into the combatant ranks, and at once set to work to make his troop the best in the regiment. When the South African war broke out, Major Duncan, as he then was, prepared at once to go out with a draft from his regiment. To his great disappointment his senior officer was sent out in charge. In due course Duncan rose to command the regiment, the name of which by this time had been changed to that of the Middlesex Yeomanry. This military side of his life is the best example, apart from his professional work, of the very thorough manner in which Duncan carried out anything he took up, but there were others. Made a Freemason comparatively late in life, nevertheless Duncan worked at the craft with such enthusiasm that in a few years he became, in virtue of his work, a Grand Officer, and there was none who knew the ritual better or could deliver it more impressively. He was a Founder of the Middlesex Hospital Lodge, the Middlesex Yeomanry Lodge, and the Middlesex Yeomanry Chapter.

Duncan was very fond of the country, and, for some years before he retired and after, he lived at Shenley and was very popular with the villagers and farmers in the neighbourhood. He was on the local Bench and founded a cricket and football club. Nothing gave him more pleasure than to invite teams down, and many an old Middlesex man will recall those very pleasant outings and the lavish hospitality dispensed by their host. He also kept a pack of harriers, and was very successful as their Master.

William Duncan, if not a brilliant, was at any rate a very fine operator. He paid the greatest attention to details, not neglecting to stop all oozing of blood because the hands of the clock would show that the operation had taken a few minutes longer, and handling all tissues with the greatest gentleness. His results were extremely good and his temperature charts were remarkably steady, in spite of the fact that he never followed the aseptic ritual to such a degree as commonly obtained in the latter years of his professional life.

LIEUT.-COLONEL JOHN ROCHE RAHILLY, R.A.M.C. (retired), died at Weston-super-Mare on December 26th, 1917, aged 73. He was educated in Dublin, took the L.R.C.S.I. and the L.R.C.P. Edin. in 1865, and entered the army as assistant surgeon on March 31st, 1868, becoming surgeon on March 1st, 1873, and surgeon-major on March 30th, 1880, and retiring on November 28th, 1888. While the regimental medical system was in force he was medical officer of the 21st Royal Scots Fusiliers.

SURGEON-MAJOR JOHN ROBB, Bombay Medical Service (retired), died at Aberdeen on December 20th, 1917, aged 74. He was educated at Aberdeen University, where he graduated M.B. and C.M. with honours in 1866, and M.D. in 1876. Entering the L.M.S. as assistant surgeon on October 1st, 1868, he became surgeon on July 1st, 1873, and surgeon-major on October 1st, 1880, retiring on November 2nd, 1889. From 1873 to 1882 he served as residency surgeon at Zanzibar, acting also from time to time as assistant political agent, and between 1882 and 1889 was civil surgeon at Aden, Surat, and Ahmedabad successively. He was the author of *A Medico-Topographical Account of Zanzibar*, published in 1889.

DR. EDOUARD DELANGLADE, professor in the Medical School of Marseilles, was killed recently by a shell while visiting a dressing station in Alsace. He studied medicine in Paris, where he was *interne*, and graduated in 1895 with a thesis on congenital luxation of the hip and its surgical treatment. He won a high position at Marseilles, where he was the leading surgeon.

Dr. FIEUX, *professeur agrégé* in the medical faculty of the University of Bordeaux, lost his life on December 9th as the result of an accident among the mountains near Grenoble, where he was in charge of a military hospital. He held the rank of *médecin-major*, 1^{re} classe, and his courage, devotion to the wounded, and operative skill won for him the Cross of the Legion of Honour. He was 49 years of age, and took his degree at Bordeaux in 1896. He was on the staff of the Bordeaux Maternity, and had a great reputation as an obstetrician and gynaecologist; he had also earned distinction as a biologist. He was one of the pioneers in the serum diagnosis of pregnancy.

Dr. FRANKLIN P. MALL, professor of anatomy in Johns Hopkins University, Baltimore, who died on November 17th, 1917, was born in Iowa in 1862, and graduated M.D. Michigan in 1883. He was appointed instructor in pathology at Johns Hopkins University in 1888. From 1889 to 1892 he was professor of vertebrate anatomy in Clark University, Worcester, Massachusetts; he next held the chair of anatomy in the University of Chicago, but in 1893 returned to Johns Hopkins as professor of the same subject. In 1915 he was appointed director of embryology in the Carnegie Institution at Washington. He was president of the Association of American Anatomists from 1905 to 1907.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

THE Senatus reported to the University Court on December 17th, 1917, that they had approved a recommendation of the Faculty of Medicine that a course on tuberculosis shall be obligatory in the medical curriculum as from October 1st, 1918, and that the course shall consist of lectures and practical instruction, open to final year students of the University. Principal Sir Alfred Ewing presided at a medical graduation ceremonial on December 19th. The candidates for degrees were presented by Professor Littlejohn, Dean of the Faculty of Medicine. Sir Alfred Ewing in the course of his address announced that 57 medical students had returned to their studies from service in the army, and 46 from service in the navy. The students of medicine attending the University now numbered 849, against 783 at the corresponding date last year; and of these 849 students 564 were men and 285 were women.

The following degrees were conferred:

M.D.—F. T. Bowerbank,* W. T. James, P. W. Lam, C. Robertson, W. E. J. Whitley.*

* Commended for thesis.

M.B., Ch.B.—G. Balsillie, A. O. L. Brownlee, D. Cook, A. C. C. Craig, Kshibendra Mohan Dey, J. W. C. Fairweather, D. T. P. Gay, R. N. Gibson, J. G. Gilruth, J. T. Godfrey, Elizabeth Harper, J. H. Kerr, V. St. C. Lucas, A. S. McKern, S. D. Nurse, W. G. F. Owen-Morris, J. E. Purves, E. G. Pyott, A. Robertson, Mary J. Rutherford, R. L. Stewart, J. A. Stirling, F. B. Sutherland, E. T. S. Taylor, P. F. V. Walsh, D. M. Young, J. W. van Zyl.

UNIVERSITY OF ABERDEEN.

THE following degrees were conferred on December 18th, 1917:

M.B., Ch.B.—J. B. Mutch, D. J. V. Pereira, H. Roger.

UNIVERSITY OF ST. ANDREWS.

THE following candidates have been approved at the examination indicated:

M.B., Ch.B.—Kathleen I. David, W. A. Fraser, Dora M. Walker.

UNIVERSITY OF DUBLIN.

THE following candidates have been approved at the examinations indicated:

FINAL M.B.—*Part II, Medical Jurisprudence and Hygiene; Materia Medica and Therapeutics; Pathology*: J. G. Holmes,* R. Resnecor,* J. J. G. de Kock,* J. C. J. Callanan,* H. B. Van der Merwe,* A. H. Thompson, J. F. Sheppard, V. G. Walker, C. D. Brink, Mary C. Sheppard, T. J. R. Warren, R. W. Shaw, C. J. Quinlan, A. Blagoff, C. H. Keller (Medical Jurisprudence and Hygiene, Materia Medica and Therapeutics).

* Passed on high marks.

FINAL M.B., B.Ch., B.A.O.—*Part II, Medicine*: Meta G. Jackson, S. A. Clark, F. W. P. Sullivan, W. Sweetnam, J. R. Brennan, C. P. Chambers, T. S. McDonald, J. B. Taylor. *Surgery*: H. L. Parker,* T. S. McDonald, J. M. Hill, W. V. Pellissier, P. A. Dormer, Margaret Wolfe, L. J. Nugent, D. S. Prentice,† Olive G. Blackburn, T. E. Hill. *Midwifery and Gynaecology*: T. S. McDonald, W. P. Elford, E. J. Lyndon, F. J. Dymoke, J. E. Jameson, W. V. Pellissier, E. E. Rollins, F. W. Godbey, E. S. E. Mack, L. J. Nugent, K. Greer, C. H. Keller.

* High marks. † To be examined in Pathology.

D.P.H. *Part I, Bacteriology, Pathology, Chemistry, Physics, and Meteorology*: R. B. Jackson.

Part II, Sanitary Engineering; Vital Statistics and Public Health; Hygiene and Epidemiology: R. B. Jackson, T. Kirkwood.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH. At the annual meeting of the College Professor William Russell was elected president, Dr. Freeland Barbour vice-president, Dr. Norman Walker treasurer, Dr. H. Dingwall-Fordyce secretary, and Dr. H. Graham curator of the Research Laboratory.

Medical News.

A BROTHERHOOD of comrades-in-arms has been formed among the Austrian military doctors.

WITH the object of promoting the study of tropical medicine in Nicaragua a medical association of the Atlantic seaboard of that republic has been founded at Bluefields.

THE American Ambassador in Rome was authorized some time ago to draw on the Red Cross for any amount up to £50,000 to be applied to relief work in Italy. On November 11th a further sum of £50,000 was appropriated to meet emergency expenses arising from the recent reverses of the Italian army.

KING GEORGE'S Fund for Sailors now amounts to £263,000, and the Council has made a distribution of £55,000 to various marine benevolent institutions, including £5,000 to the Grand Fleet fund for the relief of immediate distress among men of the Royal Navy, their widows and dependants.

THE schedule to the Poison and Pharmacy Acts, 1908, has recently been amended by the transfer of the following substances from Part 2 to Part 1: "Diethyl-barbituric acid, and other alkyl, aryl, or metallic derivatives of barbituric acid, whether described as veronal, propanal, medinal, or by any other trade name, mark, or designation; and all poisonous urethanes and ureides."

THE book on *The Organization and Methods of the Military Orthopaedic Hospital*, Shepherd's Bush, can be obtained (price 2s.; post free 2s. 3d.) on application to the officer in charge of the hospital, Ducane Road, Shepherd's Bush, London, W.12. It is not supplied direct from the printers.

THE Committee of the French Surgical Association has decided that the annual congress, which has been in abeyance since the beginning of the war, shall be held in 1918, at a date to be fixed later. The meeting will be exclusively devoted to questions of war surgery. Communications should be addressed to the General Secretary, Dr. J. L. Faure, 10, rue de Seine, Paris.

THE Japanese Ambassador in Rome has handed to the Prime Minister of Italy the sum of £62,258 to be applied for the benefit of wounded soldiers and refugees from the invaded provinces. The money was collected by a Japanese society of which the head is Prince Tokingawa, President of the Chamber of Peers, and among the promoters of the movement was the Japanese Primo Minister.

THE authorities in Berlin have decreed that on the door-plates of doctors called up by the army particulars shall be given as to the address and consultation hours of their substitutes. The army doctor who is still able to attend to some of his civilian practice must state on which days he may be consulted. These regulations have been necessitated by the many complaints of time lost in applications for urgent medical attendance from medical men found to be absent on war work.

THE Board of Education announces that the Science Museum, South Kensington, was reopened to the public on January 1st. The museum has been closed to the public for nearly two years; it has, however, been open without interruption for students. The greater part of the museum will be open free on every week day from 10 a.m. to 5 p.m. and on Sundays from 2.30 p.m. to 5 p.m. Almost simultaneously comes the announcement that the Government has decided to commandeer the British Museum for the offices of the Air Ministry, and has maintained its decision in spite of the unanimous protest of the trustees.

A MEETING of the Royal Sanitary Institute will be held on January 11th and 12th in the Town Hall, Chester, under the chairmanship of Professor A. Bostock Hill, M.D. On Friday, January 11th, at 7 p.m., Dr. Naylor Barlow (M.O.H. Wallasey) will open a discussion on the present position with regard to venereal diseases and the sufficiency of the methods now available for combating them. On Saturday, January 12th, Dr. Meredith Young (county M.O.H. Cheshire) will open a discussion on "Activated Sludge." Those wishing to take part in the discussions can obtain a copy of the papers to be read on application to the Secretary of the Institute, 90, Buckingham Palace Road, S.W.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Ailology*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC

EASY STARTING OF MOTOR CAR.

DR. J. CRYER (Manchester) writes: Any medical man who has an ordinary gas jet in his garage, attaches 6 ft. of flexible tubing, and inserts it into the air inlet of the carburettor, will find starting on a cold morning reduced to simplicity itself.

SUPPURATING THYMUS.

DR. ARTHUR J. MATHISON (Hornsey) writes that he made a *post-mortem* examination on a female infant four months old on November 28th and found a suppurating thymus, which he thinks is a very rare condition. Probably suffocation was produced gradually, as both lungs were congested.

THE JAPANESE FLY TRAP.

CAPTAIN N. S. GILCHRIST, R.A.M.C., writes: The enclosed photograph of the now famous "Japanese fly trap" may interest readers of the *BRITISH MEDICAL JOURNAL*. Out here in Egypt we can find nothing to equal it, and the heap of flies beside it represents about a week's work at a time of the year when flies in camp were comparatively few. It is quite a simple machine of two main parts, the wire-gauze cage (detachable) and the machine to catch the flies, which consists of a revolving wooden drum, driven by clockwork. The

keyhole is visible. All the trap is of dark wood varnished, except the rollers, which should be white, as the fly is at once attracted by the shiny surface. All the trap should be scrupulously clean except the rollers, which are baited with any sort of sweet filth attractive to flies; milk and sugar acts well, or watered molasses or treacle, and so does egg, blood, etc., only these are apt to dry hard, and retard the action of the clock. The fly sitting on the slowly-revolving drum is carried into the bottom of the box, which is dark; but he sees a gleam of light leading from the wire cage, and makes a rush for it. He never finds his way out again. The trap is excellent in every way, and is a Japanese patent.

TRENCH FEVER AND THE NOTIFICATION OF INFLUENZA.

TRO RONO PUBLICO writes: In view of the possibility of a new "infectious" disease in the guise of trench fever becoming prevalent in this country, would it not be an advantage to have, for the duration of the war, all cases of so-called influenza notified? Not only would treatment in an isolation hospital help to reduce the number of cases rendered unfit or practically incapacitated, but it would give opportunity for the search for the causal factor. Most isolation hospitals have sufficient laboratory accommodation for carrying out the necessary investigations, and the best results would probably be had from cases removed from houses where members of the household have returned from active service, and where there is the possibility of vermin transmission.

MEDICAL OFFICERS AND OFFICE WORK.

SUBURBAN MEDICO, while recognizing that there is a prospect of reforms being made which will obviate the complaints of lack of work from temporary officers of the R.A.M.C., writes to point out that at the present time, in every medical unit, at least one officer is practically fully occupied with the work that in the infantry falls to the company officer and adjutant—that is, courts-martial, orderly room, censoring of letters,

paying the men, inspection of kit and quarters, and the numberless office duties. The work, he thinks, could be done by a combatant officer, unfitted for further active service by wounds or disease, attached to each medical unit.

CIVIL SURGEONS IN MILITARY HOSPITALS.

C. S. writes to draw attention to the case of civil surgeons engaged in whole-time work at military hospitals who volunteered for commissions early in the war, and having been rejected as totally unfit even for home service, gave up their appointments or practices about two years ago in order to release fit men for service abroad. They were put to full work, he says, including night duty and the meeting of ambulance trains at various terminuses at all hours of the day and night. Commissions have not been given to these medical men, and they can be dismissed or go voluntarily at a day's notice. The War Office takes no responsibility for their health; if they fall ill, their pay stops whilst they are off duty; it is even a matter of some difficulty to get them into their own hospitals when sick, and while in hospital they are charged 6s. a day. As they wear no uniform, not even a badge, few people know they are serving their country. They are entitled to no gratuity, however long they have served, and they get no facilities for travelling by rail such as their commissioned colleagues do. Our correspondent submits that such civil surgeons are entitled to some official recognition and a little more generous and considerate treatment.

THE PENETRATING POWER OF A BRITISH BULLET.

DR. W. MILNER BURGESS (Frinton-on-Sea) writes: Whilst acting as resident medical officer I was called to a soldier in a billet (second floor) who, whilst cleaning his rifle, without knowing that a live cartridge was in the breech, shot himself through the anterior surface of the left femur, between the middle and lower third, causing a compound comminuted fracture (a splinter of bone being picked off the floor; the bullet passed out through the popliteal space, causing free bleeding, the man being blanched, but the posterior tibial could be felt at the inner ankle. He was removed to hospital and did well. The bullet next passed through the second floor and the ceiling of the first floor, wounding a man on the right wrist, dorsal aspect, superficially from the ulnar to the radial side; passed through the first floor and ceiling of the ground floor, missing a man's head; and struck the hearthstone, ricocheting and burying itself in the ground floor.

PHTHISIS AND CANCER IN A RURAL DISTRICT.

"M.D." sends us notes on an examination he has made of the statistics on phthisis and cancer in a parish in the south of Scotland for the period from 1880 to the present year. The parish is purely agricultural, the industry of stocking weaving at one time carried on being now extinct. The population of the parish was 1,015 in 1891, 939 in 1901, and 865 in 1911. The following figures, showing the deaths from the two diseases in the periods mentioned, may be of interest for the purpose of comparison:

Period.	Pulmonary Tuberculosis.					Cancer				
	No. of Deaths.	M.	F.	Average Age at Death.		No. of Deaths.	M.	F.	Average Age at Death.	
1880—1890 ...	44	13	31	M. 31	F. 29	5	2	3	M. 67.6	F. 65.4
1890—1900 ...	26	9	17	34	29	13	6	7	70	69
1900—1910 ...	16	8	8	35	27	8	4	4	61.6	72
1910—1917 ...	10	3	7	34	26	6	1	5	74	51.2
Totals ...	96	33	63			32	13	19		

The statistics are typical of what we are accustomed to see during the past four decades—namely, a large reduction in the number of deaths from tuberculosis (pulmonary in this instance, with one or two cases of tuberculous meningitis and peritonitis), and a slight increase in the number from cancer. The average age at death is typical of the two diseases, and the preponderance in the number of female cases is striking, also the greater age of the male cases.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
Whole single column
Whole page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

An Address

ON

THE ORTHOPAEDIC OUTLOOK IN
MILITARY SURGERY.

BY

COLONEL SIR ROBERT JONES, C.B., C.M.,

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

THE subject of this address is sufficiently comprehensive to fill a large volume, and I can only touch, and that very lightly, upon certain problems of interest. I shall, however, try to explain the orthopaedic mind in its dealings with surgical problems, and refrain from any discussion of the more abstruse principles.

A knowledge of the best way to correct deformities and restore function should involve a knowledge of preventive methods. The pathetic side of an orthopaedic centre is the collection of physical disabilities which should never have been. The inspiring fact is that in our experience hardly a case is found to whom we cannot offer help. In the early stages of the war we dealt exclusively with corrective orthopaedics. Now that we have convoys sent directly over to us we are becoming more and more profitably engaged on the preventive side.

One point which has impressed all who are seeing end results is the necessity that we should work in much closer association with surgeons abroad than we do at present. In this way we could approach problems from their point of view, and they would learn also of the later phases of their cases. It would strengthen judgement on both sides, and clarify and standardize treatment. Consultants on both sides of the Channel would find it a welcome relief to share each others' burdens. Such important questions as the primary excision of joints and fractures of the femur, and many others, require the closest consideration which can best be made productive by such co-operation.

From its original meaning the term "orthopaedic" would seem to have little application to military surgery. We know, however, that orthopaedic surgery in civil practice has long ago burst the bonds of its etymology. It has enlarged its borders chiefly in two directions—the operative and the educational. The aim of the orthopaedic surgeon is to restore functional use to disabled limbs. He has not merely to correct a distorted limb, but to help it to perform its function. A straight limb may be ineffective functionally, while a crooked one, under appropriate after-care, may be made extremely useful.

Orthopaedic surgery has enlarged its borders on the operative side by reason of the advances made in pathological, anatomical, and physiological knowledge, which have rendered it possible to perform operations leading to the restoration of physical function which, years ago, could not be considered. It has enlarged its borders in the educational direction by taking advantage of modern methods of restoring the function of the locomotor system by electrotherapy, massage, and wisely directed voluntary exercise. There is no definite operation which is essentially orthopaedic; there is no special appliance or apparatus which is the peculiar mark of the orthopaedic surgeon. A surgeon is judged good or bad from the orthopaedic standpoint by the results of his efforts to correct physical disability. Orthopaedic surgery is based on, and consists of, the recognition and practice of definite principles of treatment—whether operative, manipulative, or educational—which lead to the restoration of function in deformed or disabled limbs or muscles.

The orthopaedic mind thinks in terms of function. It has to deal with a pre-operative and a post-operative stage. The operative stage, although it may be essential, has only its proportionate value. For this reason, orthopaedic operations which are necessary preliminaries to re-education of function include the correction of gross deformities, the reconstruction of joints, grafting operations on bones, muscles, and tendons, and the repair of injured nerves. They include the maintenance of joints and limbs in proper position in order that injured tissues may recover functional efficiency. This is preventive. They involve also the correction of faulty positions of

joints by manipulations most carefully conducted by splint or by graduated support. They should also include the prevention of those pathological displacements of joints which are found too often in our wards.

It behoves surgeons generally to expand their knowledge of the principles which guide us in orthopaedics, in order to lessen the necessity, or shorten the period of disability. The early wound treatment would include certain methods which involve an efficient fixation of the limb in the position best suited for usefulness.

In these days of operative exploits it is not easy to find the mind which will be sufficiently patient to undergo a training in the slow methods involved in this special kind of work. I deplore the loss of a number of young men who have failed to resist the lure of the abdomen, and who are now hopelessly lost in that productive cavity. They are badly wanted, but very difficult to deliver.

The orthopaedic surgeon must be tenacious, hopeful, enthusiastic, and very, very patient: or he fails to supply that psychological element which inspires his patient through the mouths of weary waiting so often needed before any results of treatment are apparent.

The conditions which, taken together, create an orthopaedic case may be classed roughly under the following heads:

1. The mechanical injury to bone, joint, muscle, or nerve.
2. The atrophy and disease of these structures primarily due to the injury.
3. Inco-ordination of movement due to disease of the brain—a result of atrophy and disease of peripheral structures.
4. Psychological conditions which can be overcome by re-educational processes.

The fact that about 50 per cent. of the wounded of this war have received injuries resulting in impairment of locomotor function and usefulness of limbs has brought the importance of orthopaedic principles and methods of treatment into a prominence which no one had foreseen.

The number of wounded men is so great that they form an economic problem, not only for the present but for the future. The problem for the present is how most rapidly to make the wounded man fit for military service; or, failing fitness for military service, how are we to make him become an independent self-supporting citizen and not a crippled dependant? The problem of the future is how the partially disabled man is to be kept as fit as possible after he has left the army. This last problem is for the Ministry of Pensions to solve, and a more momentous problem, fraught with so many possibilities of success or failure, has rarely existed. There should be no gap in continuity of treatment when the soldier leaves the army and becomes the care of the Pensions Ministry.

HOSPITALS AND ACCOMMODATION.

In the early stages of the war the sudden influx of large numbers of wounded men demanded a sudden expansion of hospital accommodation. At this time also the terrible sepsis of wounds from the battlefields of France presented a difficulty for which surgeons had not been prepared by previous experience. The severe septic injuries from which the men were suffering took a long time to heal, and the wounded from other big battles began to crowd into this country faster than the hospitals could be cleared by the normal discharge of patients fully cured of their disabilities.

The pressure on accommodation was such that from time to time various orders were issued for the discharge from the army of men who would not be fit for active service within a specified number of months. The result of this was that men were discharged from the army and from hospital as soon as their wounds were healed and their general condition allowed them to leave, but they were not cured of their physical disabilities. Consequently, the civilian population was steadily becoming more and more burdened with wounded men not fit to earn their living, and not likely to become fit until they had some further surgical treatment.

This was a state of affairs which presented grave dangers from the economic standpoint. As the end of the war began to seem more remote than at first thought probable, it became clear that this hasty discharge of wounded men must cease—not only from the point of view of national economy, but also from the point of view of military conservation of man power. There was no Pensions Ministry at this time to supplement treatment,

and the Statutory Committee never found its legs, so the responsibility again fell upon the shoulders of the War Office and room had to be found for the readmission of these discharged men. They included cases of mal-united fractures, which required operative treatment; un-united fractures, many of which required bone grafting; old cases of nerve injuries requiring suture, and innumerable cases of stiff fingers, ankylosed joints, and contractures due to scars following septic wounds.

It was at this stage that Sir Alfred Keogh instructed me to start the first orthopaedic centre in Liverpool, with a view of concentrating under one roof a staff trained in orthopaedic principles and an equipment which could provide for all the stages of treatment necessary for the restoration of function. This enabled other hospitals to evacuate some of their worst and more tedious cases, and make room for more recent ones. We started in Liverpool with 250 beds, and we have now sixteen centres in the British Isles containing close upon 15,000 of our wounded. Of the men treated in these centres 75 per cent. have been returned to the army.

WHAT IS AN ORTHOPAEDIC CENTRE?

An orthopaedic centre consists of:

1. A staff of surgeons who have had previous experience of the detail of orthopaedic work, both operative, manipulative, and educational. They plan the complete course of treatment.

2. Men with experience in operative surgery who, though not specializing in the work, are interested in it, and only need experience to fit them to take charge of wards in new centres as they are formed. We are always glad to hear of such men.

3. Still younger men who will ultimately go abroad. I cannot too strongly state the advantages which orthopaedic centres offer for the training of young men about to leave our shores. These centres might be made much more educational than at present with the greatest benefit to all concerned.

4. The hospital further consists of a series of auxiliary departments, each under a medical man who has experience of the particular methods of the treatment he directs. These departments are the electric, the massage, the hydrological, the gymnastic, and the curative workshops.

The successful working of an orthopaedic centre depends upon the coherent association of all departments in carrying out the plan of campaign mapped out by the surgeon when he sees the case.

Workshops.

Workshops have proved of considerable value in orthopaedic centres. They act directly and indirectly on the welfare and recovery of the patient. They act directly as a curative agent when the work done gives exercise to the injured limb, and can therefore be employed as agents in restoring co-ordinate movements. Equally valuable is the indirect effect of being put to useful work.

Discipline, however, was for long a difficulty. In orthopaedic hospitals a very large number of men can get about, and concerts, card-playing, and smoking soon cease to be interesting occupations for a man who is well in health except for a twisted hand, a disabled shoulder, or other disability. Some occupation was necessary, and the only one which presented itself was breaking rules and the mild excitement of coming before the commanding officer and the joy of having a grievance to grumble about. It is in this connexion that the curative workshop comes most actively into play.

Workshops are being instituted in every centre as part of the psycho-therapeutic treatment as well as for the purpose of re-educating injured limbs. Splint shops exist for making all the splints required by the hospital, carpenters' shops for making things needed in the hospitals, such as gymnastic plant, racks for x-ray negatives, and all the endless repairs and alterations required in a big and growing institution. Boot shops are required for making special boots and repairing those that are worn out, and electrical fitting shops for making and repairing apparatus required in the electrical department as well as keeping the ordinary light installation in order. To these manual occupations are added others, such as clerk orderlies

to the medical officers to help in keeping records of cases, the proper filing of x-ray photographs, and so forth. In all this a point of great psychological value is that the work is productive and useful, it is work that has to be done by somebody, and the wounded man feels that if he does it at all it is worth doing well.

In prescribing curative work in the workshops—that is, work directly exercising the disabled limb—care has to be taken not to fatigue it and so impede recovery. At first every man was told to use his injured limb, but once the fact was recognized that over-fatigue might result and that the indirect use of the limb was giving better results, the workshop became more curative. In such cases the necessary amount of exercise of the disabled limb is carried out daily in one of the special departments, and later in the gymnasium.

In all these arrangements for employing a patient the value of his work as a producer is secondary. The important point is that the work shall be curative of his physical disability, and especially keep him from becoming an incurable idler.

For the initiation and equipment of all these shops and departments we are deeply indebted to King Manuel, while the generous help of the British Red Cross Society has been of inestimable value. Means of getting to work quickly were promptly forthcoming, and the success of the first schemes at once led to the supply of means for expansion and development.

THE SURGICAL SIDE OF THE WORK.

In the earlier stages the work of our orthopaedic staff included the rectifying of many deformities which might have been avoided; to-day these are becoming fewer as the fundamental principles of treatment of deformity are being earlier applied. The successful anticipation and prevention of pestilences is the most conspicuously successful feature of our medical services. A similar anticipation and prevention of deformity and disability as the result of wounds has not yet been achieved, and only when it has will the number of cases we now call orthopaedic be lessened.

THE CAUSES OF DEFORMITY.

If the number of cripples and of cases of deformity is to be reduced we must examine into the causes of deformity and the difficulties which the surgeons in the field have to overcome. Thanks to the united efforts of pathologists, bacteriologists, and other workers, a partial victory has been won over sepsis, and now that the fear of death from sepsis is lessened, we must turn with greater assiduity to the problem of saving limbs and preventing deformity.

The orthopaedic problem can be divided, therefore, into two distinct parts—preventive orthopaedics and corrective orthopaedics. The latter is more especially the department of the trained orthopaedic surgeon, and I shall return to it briefly later. The preventive requires the help of every surgeon who has to treat wounded men at any stage, especially the early stage.

GUNSHOT INJURIES OF THE FEMUR.

Gunshot injuries of the femur constitute, in my opinion, the tragedy of the war, not only by reason of the fatality by which they are attended, but also because of the deformity and shortening so often associated with them. Recent convoys show a marked improvement upon earlier ones, but much more remains to be done, and the question is very urgent. From abroad I have received bitter complaints of the want of continuity of treatment in this country; and, from our experience here, we are forced to the conclusion that while cases arrive from certain hospitals abroad most admirably fixed, they arrive from other places leaving much to be desired.

The question of fractures of the femur is essentially one of preventive orthopaedics. Our centres are constantly dealing with deformities following this injury. Many cases come with four or five inches of shortening and with every variety of deflection. Is there no way in which the better results could be multiplied, and the bad results avoided? I venture very respectfully to suggest that there is. It may involve difficulties in administration, but they should easily be overcome. From all one hears, the present mortality is far too high, and every effort should be made to standardize the treatment of fractures of the

femur on the most efficient plan. The remedy consists of leaving these fractures in the hands of specially trained men, who should be retained for this work only. They should proceed in association on a common plan. This is more than ever necessary now that it has been decided to retain these fractures in France.

Now what is the plan? First and foremost, the concentration of all fractured femurs in special fracture hospitals at the base. I would suggest that a large hospital should be reserved for these cases at each base. Each hospital should be staffed by well-trained surgeons with mechanical aptitude, desirous of devoting themselves to this special work for the term of their service. They should have security of tenure for two reasons. In the first place, more responsible or urgent work could not be found for any surgeon, and, in the second place, experience in the fracture service would constantly increase the rapidity and efficiency of their work. They should have selected nurses and orderlies to help them in team work, and they also should be protected from the danger of frequent changes. These fracture hospitals should be visited by an inspector of fractures acting in conjunction with the consulting surgeons of the various districts. No case should be evacuated in opposition to his instructions, and he should have a deciding voice in the selection or removal of any member of the surgical staff.

One or more of these hospitals should be chosen as an educational centre, and all young surgeons who can be spared from time to time should undergo training there. Certain nurses and orderlies should also be trained, and in this way teams prepared to do rapid and efficient work at the casualty clearing stations.

At present, fractures of the femur are found distributed in various hospitals—many in tents. Under these conditions continuity of treatment is impossible. Like an orthopaedic centre, a fracture hospital needs a thorough equipment. Surgeons, however able and conscientious, cannot do justice to a fracture of the femur when short of equipment and located in a tent. Even surgeons of very special experience, and they are few, are rendered comparatively impotent in these conditions. If these suggestions are followed, the saving in personnel would be very appreciable, for the work would be organized. A trained surgeon, an orderly, and a sister would do more rapid and efficient work as a team than half a dozen most excellent surgeons who do not possess this special experience. The training school could in an incredibly short time supply regimental aid posts and casualty clearing stations with teams of surgeons and orderlies taught to fix these fractures efficiently and with astonishing rapidity.*

Two fundamental principles must be sacredly adhered to:

1. Efficient fixation in correct alignment at the earliest possible moment.
2. Continuity of treatment.

Death, when it occurs early, is usually due to shock, the result of direct injury, the shock being often increased by exposure and the movement of injured tissues during transport. Fixation, therefore, should not be delayed a moment. For the purpose of rapid, simple, and efficient fixation there is no splint to compare with a Thomas. I learn that in many divisions these splints have now been supplied to the regimental aid posts. They should be supplied to all. These splints can be rapidly applied over the trousers and extension made by a pull on the boot. Twenty or thirty cases can be dealt with in an hour by a trained team of orderlies; I allude, of course, merely to the mechanical fixation of the fracture.

The wound is next thoroughly overhauled in the casualty clearing station. When this can be done with the limb well extended in the splint it is an advantage. This extension of the limb undoes all kinks and folds wherein discharges may collect. When the wound is thoroughly dealt with, and the limb fixed for permanent treatment, the case is sent down the line whenever it is safe. Experience has proved that, since such cases cannot be kept indefinitely at the casualty clearing stations, they should be sent down at the earliest possible moment after the recovery from shock, before sepsis has had time to spread and before the danger of secondary hæmorrhage

has set in. Cases do best at the base hospitals when they are received there during the first three days.

This secures for us the second important principle—continuity of treatment. The teams at the regimental aid posts, the casualty clearing stations and the base hospitals will have a common understanding, and no unnecessary change of methods is likely to occur.

How are we at home to continue the work in its final stage? An Army Council instruction has been issued directing that all fractures of the femur which come to this country shall be sent to orthopaedic centres, and in case these centres are full, to specially selected hospitals. If this instruction is faithfully obeyed our results will be enormously improved. Certain cases, however, continue to gravitate elsewhere. When this happens, I would ask surgeons to remember that, after gunshot fractures of the femur, the bones remain soft for several months after so-called union has taken place. This means that body weight on the unsupported femur will make it yield. Cases are now coming from France beautifully fitted with caliper splints which should be worn for many weeks. Some of these have been prematurely removed and bowing of the femur has resulted. Gunshot fractures of bones take a considerably longer time to harden than we have been accustomed to in civilian practice.

Both at home and abroad the defects of treatment run on similar lines—namely, inefficient reduction, fixation and extension. These defects will be mostly overcome by segregation and a carefully selected personnel. The orthopaedic centres with their equipment offer very suitable facilities, but as the numbers of these cases increase other general hospitals should be selected and supplied with whatever equipment is needed. Now that fractures are being retained abroad until they can safely travel, the railway journey on this side need not be considered. We must never forget the difficulties our surgeons abroad have to contend with, and that they have shown greater initiative and progress than we have at home. If opportunities could be extended enabling young surgeons engaged in this work in France and England to exchange visits, it would prove of great educational value.

GUNSHOT FRACTURES OF OTHER BONES.

What has been said about fracture of the femur is true of fractures of other bones of the limbs. The danger to life is less, but the frequency of deformity is as great. There are one or two types of deformity which recur so constantly that some mention should be made of them.

In the lower limb, fractures of the bones of the leg are too often associated with a backward sagging at the site of fracture, due to inefficient support; or they present a valgus deformity at the seat of fracture, which is a very serious fault, for the body weight is deflected on to the inner side of the foot, thus producing the more serious disabilities associated with aggravated flat-foot. A bow-leg is a strong leg even if it is ugly, while a valgus leg is both weak and ugly.

Non-union, or delayed union, is far too commonly met with in fractures of the humerus. This is most frequent when the fracture is through the middle third. Two factors are mainly responsible for this—over-extension and inefficient fixation. If, for purposes of drainage and fixation, extension is used, it should never be excessive or prolonged; it is an easy matter to separate the fractured ends of the humerus by an inch or more if traction is severe. The other factor is inefficient fixation. Whatever splint is used, it should enable the dressing to be applied without disturbance of the fragments, and it should permit flexion of the elbow to considerably above the right angle. The prevailing deformity in fractures of the lower end of the humerus is a backward thrust of the elbow. This is best governed by flexing the elbow sufficiently. Fractures through the elbow-joint, in view of ankylosis, should be treated at right angles. It is in this fracture specially that care should be taken to keep the forearm about three-fourths supinated, for a pronated hand with ankylosed elbow is tragic.

In this connexion I may draw attention to two serious dangers in compound fractures of the forearm. One is vicious union between the two bones, and the other is sagging or convexity to the ulnar side. Both lead to impairment of pronation and supination. To prevent these deformities we should first make sure that the ulna is in

* I have been informed since delivering this address that many of the suggestions I have outlined have already been adopted at the front.

line, and then secure supination. Any theories we may hold in regard to the action of the pronator radii teres may be discarded, for pronation of the forearm is a direct invitation to cross union. It is a sound rule in all fractures of the upper limb to see that the *palm is towards the face when the elbow is flexed*.

GUNSHOT INJURIES OF JOINTS.

The results of primary excision of joints are filtering into the orthopaedic centres. I am not in the position to criticize the value of this procedure, but surgeons abroad should know that the functional results are very bad. Flail knees, flail elbows, flail shoulders—many of them suppurating—are constantly in evidence. They present a serious problem to the surgeon. We have been able to ankylose many of the elbows with good functional result. This is true to a lesser extent in the case of knees and shoulders. Some of the excisions of the knees well above the condyles and below the tuberosities leave very little in the way of bearing surface to work upon. Indeed, in those cases amputation is often justified. We must at once admit that any surgical procedure is welcomed which will save an amputation, and this is especially true of the arm. The artificial arm is a miserable substitute for a living one, however maimed, and to amputate an arm should be almost the heaviest responsibility a surgeon can assume. Primary excisions of joints or muscles are infinitely to be preferred to a loss of limb; but is amputation always, or often, the alternative? On that point we would like an authoritative pronouncement by the consultants abroad. If the conditions admit, it is obvious that the greatest conservatism in the treatment of joints should be practised, and, with the growing ascendancy which our surgeons abroad are gaining over sepsis, I cannot but think that routine excisions should be, and doubtless are, discouraged. A procedure which may have an exceptional value should be hedged by clearly defined instructions and limitations. Perhaps such instructions already exist. Do these excisions save life and limb? Is there not some way of so improving the fixation and drainage of these injuries that less drastic measures will suffice?

We constantly receive from certain sectors gunshot injuries to joints—especially knees and shoulders—where immediate excision of the *wound* (not the joint) has been practised. The results are often surprisingly good. At one hospital we had at one time five such cases of gunshot injuries through the knee, and in three of them a perfectly functioning joint resulted, while in both the others the wounds had healed without incident. If such joints had been subjected to primary excision, what a tragedy it would have been! Should these excisions be called for, an authoritative ruling on the matter is needed, clearly specifying the types that can be spared and those that must be sacrificed.

From the orthopaedic standpoint, I may offer a few suggestions as to the after-treatment of these excisions in order that we may secure a fair functional result. If the shoulder is excised, the arm should be placed in an abducted position at an angle of about 50 degrees. The elbow should be slightly in front of the coronal plane of the body, so that when it is at right angles and the forearm supinated, the palm of the hand is towards the face. The bones should be approximated by posture at an early date. If ankylosis occurs in this position, the arm can be lifted to a considerable height by scapular action. The arm should not be left hanging, as there is on the one side a danger of a useless flail shoulder, while on the other, should it become ankylosed, the movement will be very limited. If the excision should result in a flail shoulder, it should be ankylosed in the position I have just described.

The same principles govern our post-operative treatment of the elbow. Excision of the elbow-joint with complete removal of the condyles and of the olecranon generally leads to flail elbow—a most useless elbow to a working man. On the other hand, an elbow ankylosed firmly at nearly a right angle is very serviceable.

In treating such excisions of the elbow, I should advise that they should be kept extended and supinated during the early stages of drainage, then gradually flexed to a right angle, even if sinuses discharge. If the elbow is kept straight while a suppurating wound heals, there is a danger of ankylosis in extension. If there be no

suppuration the elbow can be flexed from the first. The worst cases, for reasons which are obvious should ankylosis result, are those which have been kept straight with the forearm pronated.

In all gunshot injuries about joints, where ankylosis is feared, the arm should be placed in a position most useful for the patient in after-life: the shoulder abducted, as I have already described; the elbow at an angle of about 70 degrees flexion from full extension; the forearm nearly two-thirds supinated; the wrist in dorsiflexion, and the hip in slight abduction and external rotation with full extension; the knee in full extension; the ankle at right angles, and very slightly varoid.

INJURIES OF MUSCLE AND NERVE.

The importance of position becomes evident again in injuries of muscles and nerves. Torn muscles must not be allowed to become puckered by dense scars; the limb must be put in positions which will prevent the formation of undue contractures. This matter is one which calls for great judgement, and the surgeon should at the earliest stage encourage voluntary action of the muscle—not necessarily movement of the limb. No muscle will move voluntarily while the seat of an acute injury; so soon, however, as the injury is healed, the muscle can make movements, provided it is not heavily loaded. This is one of the important factors in re-education methods.

The surgeon has, therefore, to watch whether in the injured muscle contracture or overstretching is taking place, and act accordingly. Generally speaking, contractures occur in flexors and overstretching in extensors; but a hard and fast rule cannot be laid down, especially in positions in which gravity plays an important part.

In recovering nerve injuries, whether after bruising of the nerve followed by spontaneous recovery, or after suture for a divided nerve, the muscles supplied by the nerve must be kept continuously relaxed by splinting the limb: first, because paralysed muscles are easily overstretched, and overstretched muscles cannot contract; secondly, because relaxed muscles are more susceptible to returning trophic influences and are in a state to respond to the first feeble motor impulses that come to them through the recovering nerve. It is then that voluntary re-education can be begun. For the same reason all deformities which would impede the action of the muscle should be corrected as a preliminary to nerve suture unless this subsequent correction can be easily secured without straining the fresh union in the nerve.

CORRECTIVE ORTHOPAEDIC SURGERY.

If I have shown that the most important side of orthopaedic surgery in relation to military surgery is preventive orthopaedics, and that preventive orthopaedic treatment should be consciously and definitely recognized and practised from the moment the wounded man is first attended to, and then continuously thereafter, according to definite recognized principles, I have not entirely failed.

The question is, How are we to establish recognized methods?

One means already in existence is within our orthopaedic centres by encouraging the staffs of the various hospitals to meet and discuss their difficulties, their methods and their results, and by holding conferences at the various centres.

The next is, that each centre should be used as an educational centre, open to all who wish to see the methods practised there.

Surgeons home from the front should not merely spend one day out of their precious leave in going to look at the work because they have heard it spoken of, but some system should be organized by which all the younger surgeons should be sent for a few weeks to work in these hospitals; first, that they may compare the results with their expectations when they treated similar cases in the first instance on the field; second, that by observing and assisting in the work of corrective orthopaedics they may learn how to practise preventive orthopaedics. It must be remembered that a part of corrective orthopaedics consists in deliberately inflicting the original injury by operation, and then treating the case over again.

This is especially the case in the treatment of malunited fractures, where the operative treatment consists in re-making the original fracture and then setting it in better

position. The orthopaedic surgeon has the advantage that he waits until the risk of recurring sepsis is practically absent, but he labours under the disadvantage that scars and contractures have occurred as the result of the original sepsis, which make it difficult to get the bones into correct position.

The treatment of stiff joints, again, presents a whole series of problems. In civil practice after a sprain or injury of a joint a few adhesions often occur which interfere with its free action, and, moreover, any movement which stretches these adhesions causes pain. The treatment as a rule is simple—forced manipulation to break down the little fibrous bands of adhesions. This class of case very rarely occurs in military surgery—so rarely that I would almost say a surgeon without considerable experience of manipulative methods, when he is tempted to move a stiff joint after gunshot injuries, had better pause, reflect, and refrain. I emphasize this because I have seen so many cases in which joints have been forcibly moved with disastrous results. As an illustration, let us very briefly consider a series of hypothetical cases, types of which occur over and over again as varieties of stiff knee.

1. First assume that a small fragment of metal has penetrated the front of the knee-joint, tearing the capsule and aponeurosis, but has been removed and the wound has healed without suppuration. The movement of the joint later is limited by pain, localized to near the wound and a definite stop to movement. The knee is flexed under an anaesthetic and one or two definite snaps are felt and all is well. This is a simple case of a few fibrous bands about the capsule which were stopping movements.

2. Next we will take a similar injury followed by effusion and a brief mild suppuration in the joint, relieved by cleansing and very temporary drainage. The movement of the knee is limited on attempting movement under anaesthesia; no great resistance is felt, but there is a soft tearing sensation. The experienced surgeon stops at once. He is not breaking one or two bands but is tearing a diffuse soft fibrosis extending all through the joint, and the result of his assault will be the formation of a more dense fibrosis. By waiting until the pathological changes are ended, movement may be restored in gentle stages of persuasively conducted alternate attack and rest.

3. In another case a piece of shell has torn the quadriceps above the patella and the muscle is firmly fixed down to the bone. If the surgeon attempts to flex the knee forcibly, he runs a big risk of fracturing the patella; but if he puts the limb on a back splint, so as to relax the quadriceps completely so that there is no strain on the scar, and massages the scar, it may loosen in a few weeks and become merely a fibrous intersection in the muscle, and then movement of the knee may be commenced.

4. There has been a septic fracture of the femur, and the quadriceps, especially the vasti, have become infiltrated first with toxic fluids and later by a matted fibrous tissue. Any attempt to stretch that by force is doomed to failure and will probably lead to a fracture of the patella. The best way of attacking such a case is to apply a splint which will allow of gradual flexion in stages. It may take two or three months to restore a range of movement of 45 degrees. With that range of movement the patient can walk with a little knee action and not merely with a stiff leg. After that, by use and help, he will gradually get more and more movement in the knee as the fibrous tissue in the muscle becomes absorbed.

There are other types of extra-articular obstruction which require operative attack. This is especially the case in the elbow and knee. The obstruction is usually found in a thickened capsule very much shortened, or in muscular adhesions. The extended elbow may require the free exposure of the capsule and its division, with perhaps a plastic elongation of the triceps. By similar methods the knee may be approached. The elbow or knee is then kept for a fortnight flexed. One rule must be strictly adhered to: If a stiff joint has to be moved under an anaesthetic, the bones above and below the joint must be protected. This is especially called for where a fracture has existed.

I have spoken of the reconstructive function of an orthopaedic surgeon, and to make this attitude clear we will take a hypothetical case.

A case is presented with an ankylosed shoulder, elbow, and wrist, with the potentialities of movement confined to the thumb and two adjoining fingers. The shoulder is adducted, the elbow extended, the wrist palmar-flexed, the muscles ischaemic. The question arises, Can any use be made of this apparently useless limb, or should it be amputated? On inquiry, the surgeon finds that the patient can shrug his shoulder—the scapular muscles are acting. The first procedure is to develop power in the thumb and two fingers, then to ankylose the wrist in dorsiflexion, and the elbow at the angle best suited to the patient. An osteotomy is next planned, in order to get the arm abducted. In a few weeks the scapula

carries the humerus through a long range of movement, and the patient has secured a limb much more useful than the best of artificial arms.

Time will not allow me to touch upon the interesting problems of scars, transplantation of bones and tendons, pseudarthroses, and many other allied themes. Enough has been said, however, to lay bare the orthopaedic mind. It strives for function rather than for form, but is more content if it can secure excellence in both: it is conservative and constructive, but it desires to take the most direct road to function—be it by knife, by hand, or by snasion.

I cannot conclude without paying the highest tribute to the loyalty and enthusiasm of my American and British staffs all over the country. If I sometimes try to direct their thoughts, I hope I shall never hamper them in their endeavour to solve the fascinating problems that surround them. Finally, I wish to express my deep gratitude to my professional brethren everywhere, who have neither by word nor deed done aught but encourage me in my work and lessen my labours. Without their help and confidence and kindness I should, indeed, be powerless.

ON THE SEPARATE SUTURE OF NERVES IN NERVE TRUNKS.

By J. N. LANGLEY, Sc.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY, CAMBRIDGE.

THERE are a considerable number of factors which determine the degree of recovery from the effects of nerve severance. One of these factors is the accuracy of apposition of the central and peripheral ends of the severed nerve fibres. In man, all the nerve trunks consist of bundles of nerve fibres; each bundle has its own perineurial sheath, and is surrounded by epineurial connective tissue. The relative position of the nerve bundles alters gradually in their course in the nerve trunk. It is in the highest degree improbable that an exact apposition of corresponding bundles can be made even in a freshly cut nerve, and if a piece has been excised it is certain that exact apposition never occurs. Further, microscopic examination shows that after suture the nerve fibres growing out from the central end of any one bundle usually take a devious course, and run to several peripheral bundles.

In all cases, then, in regeneration after nerve suture, the connexion of the central nervous system with the peripheral tissues will differ to a greater or less extent from the normal connexion. The new arrangement caused by nerve fibres growing out of their course is spoken of as the distortion of the nerve pattern. The nerve pattern is distorted both on its efferent and on its afferent side. On the efferent side the central nerve cells which formerly in a limb controlled solely, say, a flexor muscle, may after regeneration control flexor, extensor, adductor, abductor or rotator muscles in varying proportion. On the afferent side cutaneous fibres normally giving rise to the different sensations of cold, heat, touch, etc., will run to muscle and tendon, and muscle and tendon afferent fibres will run to the skin. The straying of nerve fibres into others having a different function may possibly to some extent be lessened by the central fibres growing more readily into fibres of their own class than into fibres of a different class, but experiment shows that such selective direction of growth, if it occurs, is not sufficient to prevent nerve fibre of any one function growing into the peripheral end of a nerve fibre of any other function. Some readjustment of the processes in the central nervous system must, then, take place in order that reflex and voluntary movements may occur in a properly co-ordinated manner. The readjustment takes place fairly rapidly in the case of simpler movements, such as flexion and extension of the limb,¹ but finer movements are only gradually recovered and the sensory adjustment appears to take a still longer time.

In regeneration after nerve suture there is not only distortion of the nerve pattern, but a varying degree of loss of innervation. Besides the nerve fibres which grow into the connective tissue surrounding the nerve bundles of the trunk and surrounding the trunk itself, a more or less considerable number grow from efferent fibres into afferent fibres, and from afferent fibres into efferent. These can make no functional connexion with the nerve

endings to which they are diverted. The loss will tend to a decrease of muscle innervation and to a reduction in the delicacy of sensation. It may to some extent be compensated for by an increase in the number of nerve fibres in consequence of their division at the central end.

There is one other abnormality which occurs in regeneration. It was shown by Anderson and myself, by Kilvington, and by Osborne and Kilvington,² that if, after nerve regeneration, the nerve be cut above the point of union, and the central end of a peripheral branch stimulated, contraction may be obtained in the muscles innervated by other branches. This is due to the single fibres of the central end dividing into two or more fibres which pass to different peripheral nerves. Such reflected actions occurring in branching axis cylinders I have called axon reflexes. Axon reflexes may be produced not only from muscle nerve to muscle nerve, but also from cutaneous nerve to muscle nerve. In a recent case in a cat³ I obtained lively contraction both in the tibialis anticus and peroneus longus on stimulating the central end of the cutaneous branch of the musculo-cutaneous nerve, the peroneal nerve being cut above the point of suture. The effect of the division of the fibres, with divergence of the branches, will vary according to the nature of the fibres, and the nerve endings, if any, which they make. Thus, when a muscle nerve fibre divides and makes new nerve endings in different muscles, a nervous impulse passing down it will cause contraction in both muscles; and when an afferent fibre capable of giving rise to sensation divides and makes new nerve endings in different regions, we must suppose that a stimulation of either region will give rise to a sensation referred to both.

All the modifications of the original connexion of the nerve fibres spoken of above may be grouped together under the head of disturbance of nerve pattern.

From the facts given above we may conclude that any procedure which reduces disturbance of nerve pattern will make recovery more complete, and will shorten the time taken in attaining that degree of recovery which is possible in the circumstances. It must be noticed that the time at which voluntary movements are first made is to a large extent independent of disturbance of nerve pattern. The first voluntary movement occurs a short time after the nerve fibres of any muscle nerve make new nerve endings in any muscle. Although exact apposition of the nerve bundles in a nerve trunk never occurs in nerve suture, some motor nerve fibres always have an opportunity of growing into other motor nerve fibres. Now it is obvious that if each peripheral nerve ran a separate course in the nerve trunk, and these were sutured separately, the distortion of nerve pattern would be much diminished. It has, however, long been known that in the larger nerve trunks the bundles exchange nerve fibres and form a plexus, which may be spoken of as the internal nerve plexus.* It would seem, then, that in the larger nerve trunks no separation of the nerves for different muscles and for different cutaneous areas is possible. But, on the other hand, some observers have mapped out the nerve bundles of the trunk of the sciatic into anterior tibial, musculo-cutaneous, posterior tibial, gastrocnemius, and other nerve bundles. If this were so, there would be a possibility of suturing the nerves separately in the sciatic.

In view of the facts and deductions I have given above, an investigation was undertaken by Dr. Hashimoto and myself upon the connexion of the peripheral nerves with the internal plexus of the sciatic in various animals. The results have been published in the *Journal of Physiology*.³ As regards the possibility of separate suture in man, they were as follows:

The only peripheral nerves which have more than a short isolated course in the sciatic from the great trochanter to the popliteal space are the nerves to the hamstring muscles (with the nerve to the adductor magnus), the nerve to the short head of the biceps, the lateral cutaneous and external saphenous nerves, the nerve to the outer head of the gastrocnemius, and that to the inner head and soleus. All the others soon after joining the sciatic become connected with the internal nerve plexus and are mixed with nerve fibres of varied peripheral dis-

tribution. All the nerves mentioned above run for part of their course in the loose outer sheath of the sciatic before they enter the dense inner sheath. They may be regarded in this part of their course as being attached to the sciatic rather than as forming an integral part of it. When a nerve has penetrated the dense inner sheath it merely forms one of the many nerve bundles of the trunk; the cutaneous nerves and the gastrocnemius nerves can still be recognized by their relation to other bundles, but, naturally, to do so requires previous dissection on *post-mortem* specimens.

The most accessible nerves are the cutaneous nerves. They run, as mentioned by Compton,⁴ on the posterior surface of the sciatic. The lateral cutaneous nerve runs an isolated course nearly the whole length of the sciatic, but in its upper part it penetrates the thick epineurial sheath of the peroneal division of the sciatic. It is known that there is considerable variation in the relative number of nerve fibres which the external saphena receives from the tibial and peroneal divisions of the sciatic. In the cases dissected by Dr. Hashimoto and myself, the peroneal contingent arose from the mid region of the sciatic, and the tibial contingent from the lower third. Probably when the tibial contingent is larger, the additional portion, like the peroneal contingent, arises from the mid-sciatic region. The practical point is that the greater part of the cutaneous nerves given off by the sciatic to the leg can be isolated and separately sutured in a considerable length of the sciatic trunk.

The nerves to the inner and outer head of the gastrocnemius, as is known, run as separate nerves in the popliteal space and join the sciatic either separately or as a single nerve. The two nerves, or the conjoined nerve, have an isolated course in the sciatic for about one and a half inches.

The hamstring group of nerves and the nerve to the short head of the biceps run a long isolated course in the outer loose sheath of the sciatic, and in *post-mortem* specimens can be readily isolated. The latter, however, dips to the anterior surface of the peroneal division of the sciatic, and is in consequence not readily accessible in life. The hamstring nerves are embedded in a good deal of connective tissue, and a satisfactory union of their ends, whether they are left in position or sutured separately, is difficult.

As I have said, all the nerves so far mentioned are recognizable on simple inspection in more or less of their course in the nerve trunk. There are others in which the epineurium must be cut open in order to distinguish them. The posterior tibial nerve below its main muscle branches consists of two sets of nerve bundles, the bundles of each set having little or no connexion with those of the other. One consists almost entirely of the external plantar nerve and the other of the internal plantar. In the peroneal nerve there is a relatively short portion in which the anterior tibial nerve, the nervus peroneus longus (with which may be the n. peroneus brevis), and the cutaneous part of the musculo-cutaneous nerve are separate and fairly easily recognizable within the epineurial sheath. The musculo-cutaneous nerve consists of separate muscular and cutaneous portions.

Most of the muscle nerves arise close together from the internal nerve plexus, and run a variable but short distance in the trunk. They occupy definite positions in relation to one another. In the comparatively rare cases of clean severance and immediate operation, it is not outside possibility to distinguish the respective central and peripheral ends of one or more of the muscle nerves, and to suture them separately. The most promising region for this is the lower part of the peroneal nerve. Lastly, there are the peroneal and tibial divisions of the sciatic; between these there is so much connective tissue that it is a question whether in man nerve fibres spread out from one division to the other, and in most regions the separation of the trunks would interfere greatly with the blood supply to the central end. On the other hand, the relative position of the two divisions changes in their course, so that if much is excised, more or less of one division will be brought opposite the other.

All isolation of nerves causes some interference with blood supply in the isolated portions; this is of little importance when the nerves run in the outer loose epineurial sheath, but, if the inner dense sheath has to be

* A figure of the plexus of the median nerve was given by Monro in 1783 (*Observations on the Structure and Functions of the Nervous System*, Tab. xviii, Edin.). This reference I owe to Professor Thane.

opened, it may delay degeneration in proportion to the density of the sheath. It would probably be advantageous to cut away as much as possible of the epineurium. A few experiments on the sciatic of any large animal would determine whether the interference with the blood supply is serious or not.

There are, no doubt, cases similar to those mentioned above in the nerve trunks supplying the arm. The only one dissected by Dr. Hashimoto and myself was the musculo-spiral (radial); in this the muscle division and the cutaneous division ran for a considerable distance isolated from one another, a fact which suggests that in cases of severance of the musculo-spiral the epineurium should be cut open and the two parts sutured separately.

ANTENATAL SYPHILIS: SUGGESTED ACTION OF THE CHORIONIC FERMENTS.

BY

AMAND J. ROUTH, M.D., F.R.C.P.,

CONSULTING OBSTETRIC PHYSICIAN TO CHARING CROSS HOSPITAL.

CONGENITAL SYPHILIS.

AFTER alluding to the discoveries of the *Spirochaeta pallida* by Schaudinn, the Wassermann reaction, and to the treatment by salvarsan, which can destroy the spirochaete without injuring the human tissues, Dr. Routh dwelt upon the serious nature of congenital syphilis as compared with primary infection, a positive reaction in a congenital syphilitic child hardly ever, according to Mr. Charles Gibbs, becoming negative under treatment. He alluded to cases of congenital syphilis transmitted to the third generation, as related by Dr. F. W. Mott, Mr. C. Gibbs, and Mr. J. E. R. McDonagh. He believed that not only is paternal infection of the ovum by the seminal fluid possible but that it is not infrequent, the mother becoming infected (1) either previously or at fertilization if she has a genital abrasion or erosion of the cervix, or (2) indirectly during the pregnancy via the embryo (conceptional syphilis), or (3) she is infected by spirochaetes in a granule stage, the mature organism being developed only after pregnancy.

More usually, he said, the embryo is infected by the already infected mother, either by the ovum being already infected, or by infection whilst embedded in the uterine mucosa, or by transplacental infection.

Sometimes there is a "mixed transmission" of infection from both parents. With very early abortions within two or three weeks of fertilization, following paternal infection of the ovum, it is possible that the woman may escape infection, owing to the absence of any true fetal circulation.

There is evidence (1) that infection can take place by the seminal fluid (F. W. Mott, etc.) even when the father has a negative Wassermann reaction, and (2) that the spirochaete has been found in the ovum in syphilitic women (Levaditi, Ball, and others). Dr. Mott has proved that syphilis is most contagious in its earliest stages, becoming less virulent each succeeding year owing to formation of maternal antibodies, the usual sequences of pregnancies being abortions, stillbirths, diseased children dying at birth or in early infancy, and children showing no signs of disease till puberty.

Dr. Routh believed that 25 per cent. of stillbirths and abortions in urban centres were probably due to syphilis, that if only 20 per cent. were caused by that disease in urban and rural centres in England and Wales, about 27,000 deaths would occur annually during the antenatal period and the first fourteen days after birth from that cause. The mortality of illegitimate children, both *in utero* and after birth, from syphilis was at least twice as heavy. The next most frequent causes of antenatal and natal deaths were toxæmia, *ante-partum* haemorrhage,

and dystocia. Macerated fetuses are, he said, now known to contain spirochaetes in over 80 per cent., though the mature organism is rarely found in abortions before the fourteenth week (Weber).

Many cases, both mothers and offspring, show no clinical evidence of syphilis till some weeks after the childbirth.

The Wassermann Reaction.

The Wassermann reaction, when first discovered, was expected to be positive when the individual was syphilitic and negative when uninfected or cured. Anomalies, however, have appeared and require explanation. Allusion was made to cases of syphilis during pregnancy with unexpected reactions, such as the negative reaction of some women when gravid with a syphilitic child, and for some time afterwards, and the negative reaction of some syphilitic children at birth, becoming positive a few weeks afterwards when the mature spirochaetes developed.

It is recognized, and has been especially stated by Mr. McDonagh, that pregnancy in some way or other often prevents the development of the mature spirochaete and that the disease is in these cases practically arrested in both mother and child during pregnancy. This, Dr. Routh believed, occurred more particularly in cases of paternal infection of the embryo. McDonagh even says that "repeated pregnancies have undoubtedly resulted in a spontaneous cure of the disease."

Some children may show no evidences of syphilis till they get tabes or general paralysis at puberty, whilst some mothers of these children may show no symptoms till after the menopause, or escape apparently altogether. The Wassermann reaction in these long latent periods has not been adequately observed.

All these cases require some other explanations than those usually given. The original words of Colles's law are true, though the numerous and varied explanations are often faulty.

Biology of Spirochaeta pallida.

Dr. Routh then reviewed the life-history of the spirochaete, giving extracts from Dr. Mott's article, in which O'Farrel, A. Balfour, and Noguchi are quoted, tending to show that under the action of salvarsan, etc., as well as spontaneously, the mature spirochaetal spiral becomes broken up transversely into granules, and that in a suitable environment these granules are capable of development into the mature organism after a short or long period of biological activity.

Noguchi had proved that after such granules have been transferred to a passive culture medium "spiral forms again sprout out." Dr. Mott has said:

The researches of Leishman on the spirochaete of tick fever suggest the possibility of an intracellular phase of the spiral organism, and its existence in the form of infective chromidian granules. Moreover, in support of this hypothesis I may mention that Neisser, in his experimental investigations on apes, has observed that the tissues of infected animals in which no spirochaetes were demonstrable, could nevertheless be used effectually for inoculation. The spirochaete may be one form of the syphilitic organism, but there may be other minute stages analogous to the spores of bacilli.

Infection by the granules can apparently occur during pregnancy, and if the granules are kept quiescent it is probable that the infected individual (mother or child) would give a negative Wassermann reaction after the birth so long as mature spirochaetes were absent.

If congenital syphilis is to be checked before the embryo is destroyed it must be dealt with locally at its source, and from the very first days after fertilization and infection. It seemed obvious that the embryonic tissues could not during the first few hours or days produce antibodies which could destroy spirochaetes.

Suggested Action of Chorionic Ferments upon Spirochaetes.

The great changes which occur in the maternal tissues, and especially in the ductless glands, Dr. Routh said, are only gradually produced, and are, therefore, not available in the early weeks to deal with spirochaetal infection. There are, however, locally present very powerful chorionic ferments produced by the syncytial cells of the fetal chorionic villi. These ferments are present in the early days of pregnancy at the point of interdigitation of the fetal and maternal portions of the placenta, and therefore

* Abstract of valedictory presidential address to the Harveian Society of London, January 10th, 1918.

are available as a powerful chemical filter for the protection of both mother and child. Their action is primarily trophoblastic to enable the delicate chorionic villi to penetrate the uterine mucosa at the placental site, and to open up maternal blood vessels, so that the ovum may have a resting place with nutritive blood spaces round it. As a result of the destructive action of the ferments upon the maternal tissues, syncytio-toxins are formed, but appear to be normally at once neutralized by so-called syncytio-lysins, and it is believed that if either of these bodies is in excess maternal and fetal toxæmia may result, often with fatal results. These ferments have been demonstrated chemically by Abderhalden to be present in the maternal blood till fifteen days after labour, and syncytio-lysin, or a maternal antibody, is demonstrable between the sixth and fourteenth week of pregnancy.

Dr. Routh suggested that these trophoblastic chorionic ferments are not only able to break up the infective spirochaetes into granules, but can, by their continued action, keep the granules quiescent and powerless to develop into the mature organism till after pregnancy, when the ferments soon cease to be present. The biological activity of the granules, unless restrained by other substances, would then be resumed, and mature spirochaetes would be developed.

He proposed explanations of the four following problems, founded on the spirillolytic action of the chorionic ferments:

1. Why may a pregnant woman who in due course either has a stillborn or a living syphilitic child have a negative Wassermann reaction during pregnancy and for some time afterwards?

2. Why are some syphilitic children negative at birth, and for some weeks afterwards?

3. Why are spirochaetes so rarely found in abortions, even though alternating between stillbirths, in the tissues of which they are swarming?

4. How do these suggestions of the spirillolytic action of the chorionic ferments help to explain the truth of the original words of "Colles's law"?

His conclusions were as follows:

CONCLUSIONS.

My suggestions seem to point to the following conclusions, some of which are scientific facts, whilst others are non-proven, but I think logical.

1. The "granules" are the result of the "spirillolysis," or breaking up of the *Spirochaeta pallida*.

2. The "granules" are infecting agents, being in fact spirochaetes in the granule stage. They are able to develop into the mature spirochaete in a suitable environment, or may become biologically inactive and remain latent for short or long periods.

3. Chorionic (syncytial) ferments are present at the point of interdigitation of the fetal and maternal portions of the placenta. Their action is primarily trophoblastic to enable the delicate chorionic villi to penetrate the uterine mucosa and to open up maternal blood vessels, so that the ovum may find for itself a resting place with nutritive blood spaces round it. As a result of the destructive action of the ferments upon the maternal tissues, so-called syncytio-toxins are formed, but appear to be at once neutralized by so-called syncytio-lysins. If not thus neutralized, maternal and fetal toxæmia may occur.

4. The chorionic ferments (or their derivatives) are suggested as being capable of exercising their destructive properties upon the *Spirochaeta pallida*, which may either be in the maternal intervillous, or fetal intravillous tissues, both of which are in intimate relations with the syncytial cells of the villi whence the ferments arise.

5. This destructive action of the chorionic ferments upon the spirochaete breaks it up into granules.

6. I further suggest that during pregnancy it is the continued action of the chorionic ferments upon the granules which may render them latent and biologically inactive, and perhaps in a few cases may destroy them.

7. After the pregnancy, when the chorionic ferments cease to be present in the tissues of the mother and child, the granules, wherever they may be, may develop into mature spirochaetes.

8. The success or failure of the chorionic ferments to protect the mother and child from spirochaetal infection would depend upon (a) the virulence of the infection,

which tends to diminish, owing to the presence of more maternal antibodies, with each successive pregnancy; and (b) upon the source of the infection. Infection is probably most difficult to arrest in a "mixed transmission," or in a true maternal infection, where attempts at infection of the embryo would be constantly proceeding throughout the pregnancy. It is probably least severe, and most easily countered by the ferments, when the primary infection is paternal, for it may then be a single infection only, and probably not capable of repetition if the primary infection be arrested.

9. The Wassermann reaction in mother and child appears to be negative if infection has been only by spirochaetes in the granule stage, so long as the granules remain biologically inactive and the mature organisms are absent.

THE COURSE OF INSTRUCTION IN VENEREAL DISEASES.

By DAVID WATSON, M.B., C.M.,

LECTURER ON VENEREAL DISEASES, UNIVERSITY OF GLASGOW.

IN view of the recommendations of the Royal Commission on Venereal Diseases, medical schools are faced with the problem of providing their students with special instruction on the diseases popularly included under the term "venereal disease."

The recommendations of the Commission as to teaching are summarized as follows in their Final Report (Sect. v):

(27) Whether by means of compulsory attendance at a course of instruction in venereal diseases or otherwise, it should be rendered certain that every medical student has adequate practical instruction in these diseases. Every medical student should attend a course of practical instruction in skin diseases.

(28) Questions relating to syphilis and gonorrhoea should be systematically set in medical and surgical examinations, so that the knowledge acquired in these diseases by candidates for examination may be tested.

As there is no class at present in the curriculum to which it would be possible to refer the teaching of this subject, the establishment of a new class will be found necessary, and the course will require to be compulsory, otherwise only a percentage of the students will attend. No expedient, such as including a question on the subject in one of the medical or surgical papers of the final examination, especially when such question is neither set nor checked by the teacher, will succeed in ensuring the attendance at a voluntary class of the majority of students. The General Medical Council may solve the question in one of the three following ways: (a) The establishment of a new compulsory class on the venereal diseases; (b) the inclusion of the teaching of the whole subject in a compulsory dermatology class; (c) the division of the subjects between a dermatology class and a new class of genito-urinary surgery, both compulsory. The last method would be the ideal one, but, unfortunately, in addition to imposing two new classes on the student, it is a plan which it would be possible to realize at present in few medical schools owing to the paucity of genito-urinary clinics. If medical education had been allowed to follow its natural process of evolution we would doubtless have found the teaching of syphilis allocated to the dermatologist and that of gonorrhoea to the genito-urinary surgeon. But circumstances have combined to force the pace in another direction, and with attention focussed on venereal disease while genito-urinary surgery lags behind, it must be recognized that the attempt to carry out this plan would involve intolerable delay.

Of the remaining alternatives there is much to be said in favour of the venereal diseases being included in an enlarged dermatology course. By this procedure the interest of the patient, the student, and the teacher would seem to be best served. The students' curriculum is extended by the minimum, while both recommendations in Clause 27 are complied with, the patient escapes the stigma of attendance at a purely venereal clinic, and the teacher is released from an undesirable curtailment of his sphere of work. On the other hand, it will doubtless appear to the governing bodies of many medical schools that the simplest and most direct way of dealing with the question

as it stands to-day is to institute voluntary classes on venereal disease while awaiting the considered action of the General Medical Council, and certainly no divergence of opinion exists as to the desirability of conducting post-graduate classes on venereal diseases at all suitable centres.

In these circumstances it may be of service to give a short sketch of a venereal disease clinic and its course of teaching, based on the experience gained at Glasgow, where a university lectureship was established some years ago.

The lecturer has charge of a venereal department at the Royal Infirmary and also of the Lock Hospital for Women, and the instruction is given at these institutions. In each there is both an outdoor and an indoor department; in the indoor a treatment room is attached to each ward and there is a central operating theatre. The outdoor department (which should have an evening hour of attendance) consists of a waiting room, an examination room, a treatment room, and a bacteriology room, all in series.

The examination room is divided into compartments by screens or otherwise, each containing an examining table; the work is thus expedited without sacrificing privacy. An instrument cabinet, dressing tables, wash-hand basins, and a sink complete the furnishing of the room. In addition to the usual surgical instruments and sterilizer, the special instruments include cystoscope, urethroscopes, storage battery; urethral probes, knives and cauteries; catheters, Watson's sounds, flexible bougies (filiform, acorn-tipped, and olivary), hot sounds, syringes, irrigating stand, neurological basins, and salvarsan apparatus.

The bacteriology room should be supplied with a good microscope, having an oil immersion lens and dark ground illumination, an incubator at 37 C., and also stains and apparatus. Tubed media can be obtained from the regular bacteriological department as required. Wassermann tests are performed only in the regular pathology department.

The treatment room in the department for male patients should have a number of cubicles each containing a urinal, and, at a height of 4½ ft. above the urinal, a two quart glass reservoir with attached rubber tubing for the irrigating solution. The most efficient means of treating gonorrhoea we have at present at our command is the *grand lavage* method of Janet. This can quite well be carried out by the patients themselves in a standing posture, but a trained attendant must be in attendance at treatment hours. He supplies each patient with a sterilized cannula, explains the details of the procedure, sees that the whole process is properly completed, and keeps a record of attendance. With this provision, a patient suffering from acute gonorrhoea can, during the first week, attend twice daily for treatment and with decreasing frequency thereafter, at hours to suit his own convenience, and he is only required to see the medical practitioner in charge at stated intervals.

The course of instruction includes at least twelve lecture-demonstrations. By a selection of cases systematic teaching and clinical instruction can be combined. In addition each student is given the opportunity of practising the technique of the various methods of diagnosis and treatment, the class being divided into sections of not more than six for this purpose. Prominence is given to the clinical and practical features of the course.

Syllabus of Course: Twelve Meetings.

1. Historical and general survey. Acute gonorrhoea in the male: anatomical and physiological data: bacteriology and pathology. Each student collects specimens for bacteriological examination.
2. Diagnosis of anterior and posterior urethritis: treatment of gonorrhoea, practice of *grand lavage*, etc.
3. The complications of gonorrhoea and their treatment: the preparation of vaccines, etc.
4. Chronic gonorrhoea, its diagnosis and treatment: use of bougies, sounds, urethroscopes, etc.
5. Gonorrhoea in women and children.
6. Urethritis simplex: venereal sores; balanitis: technique of examination to prove patient free from infectivity: prophylaxis.
7. Syphilis. Pathology: primary syphilis: classification of chancres: demonstration of the *Spirochaeta pallida*. Each student secures and examines specimens.
8. Systemic invasion: skin and mucous membrane manifestations: Wassermann reaction: methods of taking blood and serum specimens practised.
9. Late appearances of syphilis: syphilis of internal organs.

10. Syphilis of the nervous system: withdrawal of cerebro-spinal fluid for examination.

11. Congenital syphilis: syphilis of eye and ear.

12. Treatment of syphilis. Each student during the course administers kharsivan intravenously, and also practises intramuscular mercurial injections, etc.

It will be noticed that in the above synopsis almost half of the course is devoted to gonorrhoea. This, I believe, is not an undue proportion. In no other class is there more than a passing reference to gonorrhoea, while this does not hold good of syphilis. A considerable knowledge of technique is required, particularly for the treatment of chronic gonococcal infections, and a corresponding amount of time must be assigned to its teaching. Gonorrhoea is a much more common disease than syphilis, and its after-effects are hardly less important.

In so limited a course the teaching on syphilis has to be concentrated mainly on practical points in diagnosis and treatment, and on subject matter either neglected or not fully considered by the teachers in other classes. While syphilis has to be portrayed as a complete whole, and all its manifestations displayed in perspective, the lecturers on medicine are not relieved of their responsibility for giving detailed instruction on syphilitic disease of the circulatory and nervous systems, nor the ophthalmologist with reference to syphilitic disease of the eye. Patients with nerve and eye symptoms are examined, discussed, and treated, and the knowledge of the students on these cases tested, and, when necessary, reinforced; but little more than a summary is attempted. The relative value of the Wassermann reaction in the diagnosis, and the proper place of kharsivan in the treatment, of such cases can well be demonstrated in this class.

SUGGESTIONS TOWARDS A SYSTEMATIC OPERATIVE TREATMENT OF GUNSHOT WOUNDS OF THE MANDIBLE.

BY

WILFRED TROTTER, M.S., F.R.C.S.,

CAPTAIN R.A.M.C.T., 3RD LONDON GENERAL HOSPITAL;

SURGEON TO UNIVERSITY COLLEGE HOSPITAL; LECTURER ON
SYSTEMATIC SURGERY IN THE MEDICAL SCHOOL.

The problems connected with gunshot fractures of the jaw, in spite of the attention they have received and the special provision that is now made for dealing with them, do not seem to have been carried so far towards solution that we can yet regard the treatment of these injuries as wholly satisfactory. Their clinical course is still long, painful and uncertain; in the earlier stages it is not without danger, in its intermediate stages it is apt to be distressing and disgusting to the patient and chequered by recurrent abscesses and operations, and ultimately it is still apt to leave a residue of more or less permanent deformity and disability. Doubtless much is being done for the improvement of treatment in the special institutions set apart for such cases, and it is common knowledge that notable advances in technique have been made.

One does not, however, altogether escape the impression that fractures of the mandible have perhaps been regarded somewhat too exclusively as essentially problems of dental surgery, though the skill and ingenuity of dental surgeons in attacking them undoubtedly support such a view. The very success of the specialist in securing by ingeniously contrived apparatus fixation of the fragments in the most unpromising cases tends to overshadow the difficulties still remaining in dealing with sepsis and the plastic reconstruction of the jaw.

These very problems, however, are those with which the general surgeon will necessarily have been forced to contend in treating in civil practice diseases implicating the mandible. As far as can be judged from the considerable number of gunshot wounds of the jaw that reach the London general hospitals, the difficulties both as to asepsis and plastic work met with in these cases are closely similar to the difficulties in the same departments that are met with in the treatment of malignant disease in this region. The infective processes seem in the traumatic cases to be almost exclusively of buccal origin and to display clinical and pathological characters closely similar to those that are so familiar and so comparatively easily controllable by adequate measures as incidents in the

treatment of malignant disease. It is possible, therefore, that it may be of some interest to discuss the difficulties presented by war injuries of the mandible in the light of experience gained in dealing with tumours implicating this bone.

The surgical problems met with in serious wounds involving the lower jaw may be arranged in three groups in the order of their appearance.

1. Complications Following Soon After the Wound.

Haemorrhage—especially from the soft tissues of the floor of the mouth and tongue. It may be seriously persistent or recurrent, and is notoriously difficult to control.

Acute sepsis, having the characters peculiar to infections originating from the upper alimentary tract—namely, an acute course of about a week, an invariable tendency to cause sloughing, and a liability to spread as a deep cellulitis if there is the least restraint of drainage. These infections bear some direct relation to the amount of oral sepsis, but the mere presence of teeth, however healthy, makes it possible that a considerable wound will be seriously attacked.

Secondary haemorrhage—peculiarly liable to appear from about the seventh to the tenth day on account of the limited acute course of oral infections and the tendency for sloughs to begin freely separating about that time. The fact that infections from the mouth always cause sloughing makes secondary haemorrhage an appreciable risk.

2. Complications during Healing (Chronic Suppuration, Recurrent Abscesses, and Necrosis of the Jaw).

These complications are apt to drag out the case for an indefinite period, and are doubtless to a large extent due to the special density of the bone that renders the separation of sequestra a peculiarly tedious process.

3. Difficulties of Plastic Reconstitution of the Jaw.

Relapses of sepsis after bone grafting. These may be due to the impossibility of exposing the bone on either side of the gap without opening the buccal cavity, or to the implantation of the graft in the septic scar which has resulted from prolonged suppuration. Such septic scars, as is well known, are particularly prone to cause failure of bone-grafting operations.

The opinion has already been ventured that attention has perhaps tended too exclusively to be concentrated on the fixation of the fractured ends of the bone. Now it is perfectly clear that when—as is lamentably common—there has been a large loss of bone substance, no amount of fixation can lead to reconstitution of the bone, and that it is towards the latter purpose that all treatment must be directed. If, by fixation, displacement of the fragments can be prevented until reconstitution can be undertaken so much the better, but the reconstitution must be regarded as the essential purpose and nothing be allowed to prejudice it. The prevention of displacement is certainly less important than the attainment of sound union of the reformed jaw, and there can be no doubt that if there is any clash of interests between the two objects, a strong and solid bone, even if somewhat deformed, is worth a good deal more to the patient than an insecurely united but shapely one.

For considerations of treatment, cases may be conveniently divided into three classes: (1) Fractures without considerable loss of substance, actual or probable; (2) fractures with considerable loss of substance, either actual from immediate destruction or probable from necrosis, but with the superficial soft parts more or less intact; (3) fractures with considerable destruction of bone and of the overlying soft parts—cases where the bone and lower part of the face are “blown away.”

The first class obviously lends itself to treatment by intrabuccal fixation, and may be expected to give results almost as good as those of the ordinary fractured jaw of civil practice. The third class would lead us into too detailed a discussion of technique for the purposes of this paper, and so will not be entered upon. It is the second class which particularly interests us here; it seems to be an especially common and troublesome type, and perhaps to lend itself to a more radical and systematic treatment than it usually receives.

In a case of this class, with, for example, considerable destruction of the bone in the incisor or premolar region, and extensive wounding of the floor of the mouth and tongue, while the lower lip and cheek remain intact, one of the outstanding features of the early treatment is the extreme inaccessibility of the wounded soft parts. Should serious haemorrhage occur, the ordinary methods of control are almost helpless, and the surgeon may even be tempted

by the desperate—and here more than ever valueless—expedient of distant ligature. The same inaccessibility is apt to baffle him in attempting to deal radically with sepsis either by way of prevention or cure.

Now in the treatment of malignant disease in this region there is one measure which has thoroughly justified itself when it is practicable, as means of preventing both haemorrhage and sepsis, and that is the complete closure of wounds. By this is meant not the mere bringing edge to edge of mucous membrane, but the complete obliteration of cavities by bringing raw surfaces into contact by means of large mattress sutures. To do this properly, of course, full access to the parts is essential, and this will always have been obtained by the preliminary exposure of the tumour, which is indispensable before the proper removal of it can be begun.

There appears to be no valid reason why the treatment of gunshot wounds of the jaw and mouth should not have the benefit of the same free access, and there certainly is no other means of preventing haemorrhage and sepsis with the same precision that is attainable in the treatment of malignant disease.

Free access to the whole wound by uncompromising division of the overlying soft parts in order to allow of such excision of the wound surfaces as seems necessary and subsequent suture is the first suggestion, then, which a consideration of general surgical principles provides.

When a segment of the mandible has been removed for a growth the only method of securing the ends of the bone from infection and necrosis—unless the mouth has long been edentulous and is therefore comparatively aseptic—is to seal off the raw surfaces of bone by stitching the soft parts over them. To do this effectively it is necessary to bring the soft parts on the inner side of the jaw into firm contact with those on the outer side by large mattress sutures passing deeply into the floor of the mouth and tongue and tied externally on the cheek. If part of the tongue has already been removed, an adequate raw surface will be ready. Otherwise the mucous membrane is stripped off the side of the tongue to make a surface to meet the inner surface of the cheek. The soft tissues are thus brought into and completely close the gap in the jaw. In order to get the jaw thoroughly covered by soft parts it is usually necessary to bevel off the alveolar margin on each side of the gap so that no sharp angle of bone projects upwards here and is difficult to cover in. By these means haemorrhage is arrested, sepsis in the soft parts and bone is controlled and rapid union is secured, so that the resulting scar shall be comparatively aseptic and tolerant of a bone graft. No attempt is made to close the gap in the bone at the primary operation, and the surgeon concentrates his attention on getting the quickest possible healing of the wound.

The Primary Operation.

It seems probable that the same technique could be applied to certain gunshot wounds. This would involve radical operative treatment at the earliest possible moment. If it were established by x-ray examination that considerable destruction of bone had occurred and possibly that further loss by necrosis was probable, it would be clear that no attempt to secure union by ordinary methods was possible, and that everything must be done to favour the success of the necessary plastic operation.

A preliminary puncture laryngotomy should be done—a matter of a few seconds—and the pharynx plugged, or an intratracheal anaesthetic given. The fracture should be exposed either by a free incision over it or by turning back the soft parts in a flap from the middle line, and thus avoiding paralysis of the lower lip, loose fragments of bone should be removed, the wound in the soft parts excised, a clean surface given to the fractured ends by a saw cut, and the alveolar border cut back at an angle. The cheek and the floor of the mouth and side of the tongue should then be brought together with numerous large mattress sutures so as completely to obliterate any cavity between the ends of the bones. A large opening should be left for drainage below the jaw. If intrabuccal fixation of the fragments is possible now, it should, of course, be used, and will doubtless favour healing and the comfort of the patient. If such treatment were successfully carried out and healing were reasonably rapid, the necessary plastic operation should be possible within a few weeks.

The Plastic Operation.

Plastic operations on the mandible are rendered especially difficult by irregular scars in which it is impossible to bury a graft without opening the cavity of the mouth, and by septic scars in which operative interference precipitates a relapse of infection. We have considered the possible means by which these difficulties may, perhaps, be combated.

Aseptic union will, however, probably always be exceptionally difficult to attain, and it thus seems a reasonable precaution to make special efforts to maintain the vitality of a graft implanted in the jaw. To attain this object an obvious method is the use of pedunculated grafts. Such grafts can be provided by excising a piece of bone to which a muscle is attached and using the muscle as a pedicle. Parts adapted for such a purpose within reach of the mandible are the attachment of the sterno-mastoid, splenius or trachelo-mastoid to the skull, the trapezius and the levator anguli to the clavicle or scapula, but especially the attachment of the sterno-mastoid to the inner end of the clavicle. The bone here closely resembles the mandible in texture, the upper half of it with the broad attachment of the muscle lends itself to detachment and to displacement without undue difficulty into the gap in the jaw. It is unnecessary to indicate the technical steps of such an operation; the graft should obviously be measured exactly and drilled for screws before detachment. In a presumably aseptic scar there would clearly be no objection to the use of a Lane's plate if thought desirable. In a suitable case where the anterior part of the jaw had been destroyed I should not hesitate to make use of a graft from each clavicle, joined in the middle line by a suitable bent plate.

Conclusion.

In this very summary sketch it has been attempted merely to apply principles gathered in a prolonged experience and study of operations upon the jaw undertaken in civil practice in cases where large parts of the bone have had to be removed. In such cases the plastic reconstruction of the jaw has not proved to present insurmountable difficulties as a rule, and grafts, taken almost invariably from unaffected parts of the jaw itself, have been found an easy and satisfactory method of re-establishing the continuity and stability of the bone. It should be added that as in these cases some part of the thickness of the bone usually is available for use as a graft, even in the affected region, the two-stage operation is not often necessary; it is, in fact, only quite recently that one has become interested in its possibilities and in the development of its technique.

One cannot, of course, do more than suggest the technique that might be found applicable by those who have opportunities of dealing with gunshot wounds on a large scale. It seems certain, however, that the primary and immediate operation giving full access to the fracture with the purpose of limiting hæmorrhage, sepsis and necrosis and attaining a limited and relatively aseptic scar, is an indispensable preliminary to a systematic application of plastic bone surgery to large destructive lesions of the mandible. It would obviously be irrelevant in a more or less speculative paper such as this to attempt to embody all the many minor details of practice one has found useful in what I have called the primary operation as carried out for tumours. If the surgeon keeps clearly in mind the principle that protection of raw surfaces in order to secure rapid union must be the first consideration, the minor procedures that facilitate this will suggest themselves readily.

SOLVENTS FOR DICHLORAMINE T.

BY

H. D. DAKIN, D.Sc., F.R.S.,

AND

E. K. DUNHAM, M.D.

(Report to the Medical Research Committee.)

DICHLORAMINE-T is a slightly yellowish solid, readily soluble in most organic solvents with the exception of the paraffin hydrocarbons. It is a powerful antiseptic, and when dissolved in oily media has found useful application in the treatment of infected wounds¹ and for nasopharyngeal disinfection.² Although, as first stated,

dicloramine-T readily dissolves in most organic solvents, the majority of these solutions are of no value for practical purposes, since the dicloramine-T contained in them is rapidly decomposed. Among the few solvents which give reasonably stable solutions many had to be rejected on account of their proving too irritating, so that it will be realized that the selection of a suitable solvent for dicloramine-T is a somewhat difficult problem.

In our earlier experiments we made use of eucalyptol which had been previously lightly chlorinated to reduce its avidity for chlorine. The solution thus prepared was diluted with paraffin oil which had been chlorinated in similar fashion.³ Eucalyptol prepared as described is a good solvent for dicloramine-T, and the solution is reasonably stable if protected from light. Thus an 11 per cent. solution after standing in a corked amber bottle for six months still contained 6 per cent. of unchanged dicloramine-T. The addition of paraffin oil to the mixture is apt to reduce its stability, especially if care is not taken to select a suitable oil. It appears worth noting that liquid paraffin oils vary greatly in their suitability as diluents for dicloramine-T solutions. The Russian oils containing much naphthenes are unsuited for this purpose, while some grades of American oils contain considerable quantities of olefines as well as naphthenes.

The best oils with which we are acquainted are Pennsylvanian oils which have been well purified by agitation with fuming sulphuric acid and then washed and dried. Such oils are readily obtained in the open market, and on light chlorination, as previously described in this JOURNAL, furnish a very satisfactory diluent.

The use of eucalyptol has two disadvantages. In the first place, it is not as bland and innocuous a substance as might be desired, and its use is occasionally followed by a rash. Secondly, pure eucalyptol is not available in indefinitely large amounts, and at the present time its high price is a definite consideration. The same disadvantages apply to a more highly chlorinated eucalyptol, which was introduced by Lewis and Kraus, obtained by chlorinating eucalyptol with chlorine gas until the oil has a specific gravity of about 1.2. This oil, moreover, occasionally liberates traces of hydrochloric acid on standing, which causes a rapid deterioration of the dicloramine-T solution.

We therefore undertook a systematic survey of other possible solvents for dicloramine-T with the object of finding a cheaper and blander substitute for eucalyptol. This we believe we have accomplished, at least in part, and a description of the new solvent is appended. Early in our quest it became clear that most compounds containing oxygen gave unstable solutions of dicloramine-T unless the oxygen were in an ether-like combination, as in eucalyptol. Many esters, chlorinated aldehydes, acetals, alcohols, and glycerides were tried and abandoned. Chlorinated phenolic ethers, such as dichloranisol, were tried and found too irritating. It appeared improbable that compounds containing oxygen were likely to prove successful, since they usually abstracted chlorine from the dicloramine-T too readily. The choice then practically resolved itself into halogen derivatives of other hydrocarbons of the aromatic, aliphatic, and other series. The chlorine derivatives of aromatic hydrocarbons in most cases were found too irritating for practical use, and the same is, of course, true of some of the lowest members of the aliphatic series, such as chloroform. We therefore turned to the chlorine derivatives of the higher aliphatic hydrocarbons. Heptyl chloride, obtained by the chlorination of purified heptane from petroleum ether, gave encouraging results, and the same was true of many of its homologues; but it soon became clear that the stability of the dicloramine-T solution depended to a considerable extent on the purity of the solvents, and the preparation of these substances in an approximately pure condition is a difficult and costly matter. On attempting to chlorinate higher hydrocarbons, such as those in gasoline, kerosene, vaseline, and purified liquid paraffin oil, we found that with restricted chlorination poor solvents were obtained, while on more extensive chlorination deep-seated decomposition occurred with the formation of thick oils which were unusable. This latter decomposition we believe to be largely due to the presence of cyclic hydrocarbons, so-called naphthenes, in these oils, for these substances do not give simple stable derivatives on chlorination, but undergo far-reaching decomposition.

We therefore experimented with the chlorination of paraffin wax, since this substance is free from naphthenes

and is almost entirely composed of the saturated aliphatic hydrocarbons of the $C_n H_{2n+2}$ series. We found that paraffin wax could be readily chlorinated under easily regulated conditions, and that the product when prepared as described below was an extremely bland rather viscous oil, which readily dissolved dichloramine-T, and that the solutions so prepared were stable over long periods if kept under suitable conditions. As was to be expected, the product is not a single individual compound, but a mixture of isomeric and homologous chlorine derivatives. It is therefore impossible to give a systematic name to the product, and, as the descriptive name "chlorinated paraffin wax oil" seems unnecessarily clumsy, we have provisionally chosen the name "chlorosane," since the systematic names of most of the hydrocarbons in paraffin wax end with the suffix "cosane."

Preparation of the Solvent "Chlorosane."

Paraffin wax, preferably melting at 50° C. or higher, is placed in round bottomed flasks and heated to about 120°. Two flasks connected in series, each containing a half kilo of the wax, may be conveniently used. A rapid current of chlorine from a cylinder of the liquefied gas is then passed through the molten wax in the flasks, each of which is provided with a thermometer and the necessary glass tubes. The temperature should be controlled within the limits of 125-140°. The first flask in which the reaction is most vigorous will require but little heating. Chlorination is continued until the contents of the flasks have increased in weight 45 to 55 per cent. of the weight of wax taken. It will be found convenient to complete the chlorination of the first flask and then remove it, and transfer the second to its place, putting a fresh flask of paraffin wax after it. In order to avoid undue discoloration of the product, a minimum amount of rubber tubing should be used for the connexions. Wide glass tubing should be used for passing the gases, and the ends of the delivery tubes are preferably blown into bulbs provided with a number of fine orifices to promote good contact between the gas and oil. Hydrochloric acid is, of course, evolved freely during the reaction. After the requisite amount of chlorine has been absorbed, the oil, while still warm, is shaken vigorously with 5 per cent. of its weight of dry sodium carbonate and then filtered through a dry fluted paper. The clear oil, which has a light yellow or sherry colour and is slightly heavier than water, is then ready for use. It possesses a viscosity intermediate between that of olive oil and castor oil, has almost no odour, and is perfectly bland when sprayed up the nose or placed on skin or wounds.

It will be noted that the materials necessary for making the new solvent are all easily available at very cheap rates.

We have been unable to find any references in chemical literature to a product of the kind described. Lippmann and Hawliczek¹ heated paraffin wax with phosphorus pentachloride and obtained evidence of the formation of mono- and dichloro- derivatives, while Bolley,² by the exhaustive chlorination of paraffin wax, obtained solid products of varying composition. The chlorine in "chlorosane" is mostly in a firmly bound condition not readily removable by treatment with boiling alkaline solutions. It does not react with metallic magnesium suspended in ether, but on heating with soda lime to 250° unsaturated hydrocarbons and a little fatty acid are formed. Boiling with aniline removes most of the chlorine with formation of complex bases which have not been closely characterized. "Chlorosane," itself containing all its chlorine united to carbon, has, of course, no appreciable antiseptic action.

Preparation and Stability of Solutions of Dichloramine-T in Chlorosane.

Chlorosane at room temperature can dissolve from 8.5 to 10 per cent. of dichloramine-T. For wound treatment a 7.5 to 8 per cent. solution is strong enough for all purposes and is most conveniently prepared as follows: A portion of the oil—for example, a quarter—is heated to 75° or 80° C. and the weighed amount of solid dichloramine-T is then added. The latter substance will promptly melt and dissolve in the warm oil, which is then at once diluted with the remainder of the oil and the whole well mixed. If necessary, the solution can be filtered, but with pure materials this is not required. The clear solution should be at once stored in small amber corked bottles and not exposed to unnecessary heat.

Direct sunlight causes the most rapid decomposition of dichloramine-T solutions, and it should also be noted that blue glass bottles afford no protection. If kept in amber bottles, the solutions remain clear and retain their activity practically unimpaired for many weeks or possibly months.

Two preparations containing initially 8.7 and 8.9 per cent. dichloramine-T, kept for one month in corked amber bottles at laboratory temperature, contained 8.2 and 8.4 per cent. respectively at the end of that time. A similar oil exposed to direct sunlight for four days was completely decomposed, while another sample incubated at 40° C. fell from 8 to 3 per cent. in a month. Under ordinary conditions solutions which are protected from light by amber bottles and from contact with water or excessive heat may safely be used for two months or possibly longer.

The clinical results of dichloramine-T dissolved in the new oil are similar to those already recorded by Lee, Sweet, and others, and the same is true of its disinfecting action in the nasopharynx. The only difficulty that we have thus far encountered is the fact that the high viscosity of the oil prevents its being readily sprayed with a hand spray, though this is easily accomplished with a power spray. The addition of about 10 per cent. of carbon tetrachloride will reduce the viscosity of the mixture to a point at which it can be readily sprayed in an ordinary oil "atomizer." This dilution has no deleterious effect on the stability of the solution and is unobjectionable for wound treatment. It appears desirable to add the carbon tetrachloride only to the oil used in the hand spray and to use the thicker oil undiluted for other modes of use.

A SKIN INK FOR RADIOGRAPHY.

BY

CAPTAIN N. S. FINZI, M.B.,
1ST LONDON GENERAL HOSPITAL.

RADIOLOGISTS have long been troubled by the thorough way in which some nurses endeavour to remove localization skin marks as soon as the patient returns to the ward; hence the need for a substance which will make an indelible mark on the skin, proof against rough treatment, has been acutely felt in this war. The properties required in such a substance are as follows:

1. It should stain the skin such a colour that it will show up against iodine.
2. The mark should be unaffected when rubbed with spirit, acetone, ether soap, or tincture of iodine.
3. The mark must last, when covered up with dressings, at least five days, and longer if possible.
4. The mark should be quickly and easily made, and making it should not hurt the patient, for it must often be placed on a part that is acutely inflamed and tender.
5. The substance used for the mark must not damage or inflame the skin.
6. The mark should be visible immediately it is made.
7. The materials used must be obtainable.

Condition 4 practically requires the use of a liquid applied with a brush, as the pressure of a pencil often causes considerable pain. The liquid should penetrate the skin well, and evaporate quickly, so that watery solutions are ruled out; and it is advisable, in order to save time, to have a single-solution marking fluid.

Silver nitrate forms a good mark, but it turns white with iodine and is not easily seen. It cannot be seen when first applied, it must be used in aqueous solution, and it may cause a good deal of inflammation when developed *in situ* by photographic developer. This substance cannot therefore be regarded as at all suitable.

I experimented with a number of dyes without finding a thoroughly satisfactory one. A solution of ferric chloride in alcohol, followed by a solution of haematoxylin in alcohol and ether, as suggested to me by Captain C. E. S. Phillips, formed a satisfactory mark, but being in two solutions took some time to apply, and, as haematoxylin is no longer obtainable, it need not be further considered. The least unsatisfactory aniline dye was a solution of methyl violet in acetone and water 50 per cent. followed by a painting with tincture of iodine. Aniline green also gave a fairly satisfactory mark when applied in the same way.

I eventually found that ferric chloride followed by pyrogallie acid gave a grey mark, which gradually turned a

* The ordinary indelible pencil appears to contain this dye.

fine black after five or six hours, and this mark lasted more than double as long as the iron-haematoxylin mark when exposed to the same conditions. Further, the mark was unaffected by iodine, acetone, ether soap, etc., and could, in fact, be scrubbed with a nail-brush and ether soap two days after it was made without being completely removed.

Experiments were next carried out in order to obtain the fluid in one solution, and it was found that a mixture of the two solutions was quite satisfactory and seemed to keep well, showing no great tendency to oxidize even when kept in an open test tube. This is possibly due to a small amount of acid in the liquor ferri perchlor. from which it was prepared. The next points to find out were a satisfactory concentration and the best proportion of the ingredients. The latter was determined by painting the skin with a mixed solution of known constitution, and then, when dry, painting marks on it of solutions of pyrogallie acid and ferric chloride respectively. If one or the other improved the result the mixture was amended accordingly. The former point was disclosed by a series of comparative marks with different strengths.

Different skins seem to vary in the degree to which they take stains and as to the durability of the resulting marks. Experiments with different solvents showed that acetone and methylated spirit gave little difference in result on my own skin, the latter, however, was better than rectified spirit. Owing to the greasiness of some skins it seems advisable to make the fluid, at any rate in part, with acetone, though if this is not obtainable, methylated spirit may be substituted.

The formula I finally arrived at was—

Acid, pyrogallie.	1 gram
Spirit, vini meth.	10 c.cm.
Liq. ferri perchlor. fort.	2 c.cm.
Acetone	ad 20 c.cm.

This gives a concentration of 5 per cent. pyrogallol and 2 per cent. Fe. The solution is best kept in a bottle with a camel's-hair brush attached to the cork so that it can easily be painted on. The mark is a brownish-grey at first, but after a few hours turns a brilliant black. It fulfils the conditions set forth above.

DRAINAGE v. SCRAPING IN THE OPERATION OF CURETTAGE OF THE UTERUS.

BY

G. S. THOMPSON, F.R.C.S.Eng.,
RANDWICK, SYDNEY, AUSTRALIA.

THE object of this paper is to protest against the recent modification of an old and good operation, which is nothing but bad and is tending to bring a good operation into discredit. The new-fangled procedure is to dilate the cervical canal by a three-bladed dilator just sufficiently to allow the passage of a small curette, the dilatation being often to about the calibre of a lead pencil. In the original operation the canal was dilated as much as possible, and safe, to the size of the largest Hegar dilator. I shall give my reason for thinking that this is the proper procedure.

Any benefit derived from the so-called operation of "curettage" is not from the scraping, but the drainage which dilatation to introduce the curette involves. Apart from removal of soft breaking down and loose mucous membrane by gentle use of the curette. I suggest that the results of the "curettage" operation would be at least as good if no scraping were done. The persistency of leucorrhoea is due to the inadequacy of the lower opening of the uterine cavity to permit drainage of what is virtually an open abscess cavity. For the same reason it is absurd to treat whites with douches: the drainage of the uterus (without artificial interference) through the tightly-closed cervical canal into the vagina being inadequate, the discharge tends to find its way along the path of least resistance to tubes and ovaries. If the condition is analogous to the persistent discharge of an inadequately drained abscess cavity and a condition demanding prolonged drainage, it seems obvious that to dilate the vent to such a slight degree that it rapidly closes again is absurd. We must revert to the old Hegar method, amplify it and not worry too much, if at all, about scraping; drainage is the important thing, and dilatation

must therefore be thorough, must be maintained for an adequate time, and the surgical principle of making the drainage opening at the most dependent part must not be disregarded. The cervical tissues must be rendered soft or the operation commenced after preliminary use of a laminaria tent, or following the period. The cervical canal must then be dilated to the full Hegar size. If the curette be used, it must be gently. I have found that application of iodized phenol makes little difference; if it is of benefit, I imagine it acts not by destroying germs but by determining blood to the part, and thus favouring the flow of serum. The cavity of the uterus being wiped out, one of the tubes illustrated should be inserted to maintain the dilatation and be used for a few days or a week. A thioline pessary is inserted in the vagina, and then a little gauze, and the patient put to bed; the top end of the bed is raised on blocks to facilitate drainage from the uterus. As soon as the patient is able she gets up and remains up, so as to place the drainage opening at the most dependent part. Using this operation for drainage instead of scraping I have had the most gratifying results. If the drainage tube tends to fall out, a small amount of iodoform gauze is placed at the top of the vagina. Every night for about two to three weeks, when the patient goes to bed, a thioline pessary is placed in the vagina.

The tube is a modification of a tube for which I am indebted to a previous contributor to the JOURNAL. It is about 2 inches long, slightly flanged at the vaginal end. At the upper third (uterine end) there is a slit to allow of the escape of exudation, and about three-eighths of an inch from the end around the tube is a ring to prevent the tube coming out of the cervical canal. At the flanged end is a small aperture for a silk thread to allow of easy extraction. Tubes have been made in five sizes, uterine diameters 3/16, 4/16, 5/16, 6/16, 7/16 of an inch, by Messrs. Allen and Hanburys. The smaller tubes could be used for drainage in leucorrhoea without an operation after preliminary dilatation by a laminaria tent. Many cases of whites can be cleared up or improved by such procedure if the drainage is maintained for a suitable time. Instead of curettage we might call this operation drainage of the uterus. It is a valuable prophylactic operation against damage of ovaries and tubes and the necessity for their mutilation and removal later. The tubes will also prove of value in maintaining dilatation for spasmodic dysmenorrhoea.

MEDICAL, SURGICAL, OBSTETRICAL.

MILK SUBSTITUTES FOR THE SICK.

IN view of the present scarcity of milk it seems urgent that we should reconsider our present custom of feeding sick adults on a diet more or less composed of milk. There are, of course, many for whom it is essential. On the other hand, there are great numbers for whom it is not necessary and some for whom it is not even desirable. Indeed, there are not a few to whom it is repugnant.

In a hospital dietary before me the diet of every patient contains 1½ to 3 pints of milk daily, unless specially ordered otherwise. Now, is there any real difficulty in giving a digestible and sufficient diet without milk to a large proportion of these invalids—let us say, to many surgical, cardiac, and mild febrile cases? The fashion is to a great extent only of recent origin, and a peculiarly British one. We have not, indeed, the advantage our Continental friends possess in their light and harmless bouillons, potages, and ptisanes, nor are our patients (unfortunately) accustomed to them, nor have they the mild non-intoxicating breakfast beers of our forefathers, but the chief reason for the popular use of milk as a staple food for the sick, apart from its harmlessness and digestibility, is the ease of preparing it, which saves so much work to friends and nurses in a sick house. In many cases

it involves no troublesome prescription or cooking at all. However, it is neither a perfect food for adults nor is it always well digested, and the dangers of contamination are considerable. Patent foods we have in abundance, but their cost is serious and, to poor patients, often prohibitive. They are very well as an addition to the staple food or in special cases.

I recently asked an educated Chinese gentleman what they fed their patients on in China, where, as in many countries, milk was unobtainable. His reply was briefly, "Rice boiled to a liquid and suitably flavoured." To some extent only would this meet our needs.

The ordinary sick person requires a food which is liquid, and therefore easy to take, one very easy to digest and without a strong flavour, one especially which is cheap and easy to prepare, but it need not in many cases supply a very large amount of nutriment, particularly in brief illnesses or where the patient is allowed to supplement it with bread, farinaceous puddings, eggs, butter, meat juice, or fish. The use of milk for children, or for tuberculous, renal, and miasmatic cases is another matter, and to such as these it might be restricted.

Pulped rice can be made very similar to milk in appearance and flavour, but the protein and fat are extremely low. One of the best substitutes for milk in this country is a preparation of oatmeal with or without maize. If 4 oz. of rolled oats are thoroughly boiled and then—a little diastase having been added—allowed to stand in a warm place, some 5 to 10 per cent. of the starch is converted into maltose. If they are then strained, and water is added to a pint or a pint and a half, we get a liquid very like milk. The bitter flavour of gruel is to some extent got rid of by the malting process, and the slight sweetness renders it palatable. If we get the whole full value of the oats in liquid form we should have 460 calories, or more than that of a pint of milk, but in any case we have a nutritious and easily digested liquid food.

Ground rice treated in the same way is even better in colour and flavour, but we cannot expect the same nutritive value. The same may be said of wheaten meal when boiled, malted, and strained. Under the present regulations it is impossible now to obtain ready malted oatmeal which would shorten the process of making oatmeal.

However, this is only one of many ways in which we might obtain a substitute for milk for many of our sick. If some satisfactory method was agreed on, it should be easy to get it ready-made from a communal kitchen or private firms at a price much less than that of milk to-day.

Clifton, Bristol.

GEORGE PARKER, M.D.

TWO CASES OF FILARIASIS.

THE interest of the following two cases lies in the fact that they are, I believe, the first recorded from the Hedjaz or Red Sea littoral of Arabia, and that they are samples of cases which, on inquiry, I find to be very common in that area. One informant told me that in Jeddah there were hundreds of people with enlarged testicles and swelling of the scrotum.

Mosquitos (*Culex*, *Stegomyia*, and *Anophelines*) abound in Jeddah, and, apart from the local reservoir of infection, fresh sources become available each pilgrim season, when many pilgrims from Central Africa, where filariasis is rife, pass through.

It is curious that at Suakin, on the Sudan Red Sea littoral, where the conditions are practically identical with Jeddah, even to it being a town through which many pilgrims pass, the disease is unknown.

CASE I.—A male Egyptian, aged 40, a greengrocer, who had lived in Jeddah all his life, except for a visit to Egypt eight years ago, complained of a swelling in the right side of his scrotum, which, when it first appeared five years ago, was painful, but subsequently only caused inconvenience on account of its weight and size. There was a history of two attacks of gonorrhoea twenty-three years ago, and of attacks of fever lasting for a few days at a time. The patient, who appeared in good health, was found to be suffering from a large right hydrocele with some thickening of the cord; the left testicle and cord appeared normal. At the operation the parietal and visceral tunica vaginalis testis was found thickened, indurated, and ecchymosed, and the contained fluid was blood-stained and cloudy.

CASE II.—A male Jeddawi, aged 35, a porter, who had lived at Jeddah all his life, complained of what he thought was a right inguinal hernia of seven years' duration. Patient appeared in

robust health, and in the right inguinal region, extending from the interior abdominal ring to within an inch of the top of the testis, was found a tense swelling with no impulse on coughing. On lying down the swelling got smaller but did not disappear; it then seemed to be fluid confined in a thin-walled half empty sac. The remainder of the scrotum and contents appeared normal. No obviously enlarged lymphatic glands were felt, the urine was normal, and there was no swelling of lower extremities. A lymphocele was diagnosed, and patient advised that no operation was advisable unless a hernia should develop later.

The blood of both these patients when drawn at night-time was found to contain embryos of *Filaria bancrofti*—in that of Case I about three to four to a drop, in that of Case II as many as ten to fifteen. No embryos were found in the blood drawn during the day.

Two other patients from Jeddah came for treatment at the same time as the above, one with a double hydrocele with thin-walled sac and clear fluid, and the other with a large right lymphocele, small right hydrocele, and some epididymitis of the left testis due to a recent attack of gonorrhoea. The lymphocele had been noticed for twelve years. The patient was operated on, as the nature of the condition was not recognized previous to operation.

No filariae were found after repeated examinations of the blood of these patients, although, at any rate in the case of the lymphocele, I suppose that at some time or other they must have been present.

NOEL E. WATERFIELD, M.B., B.S. Lond., F.R.C.S. Eng.,
Senior Medical Inspector, Medical Department,
Sudan Government.

DIFFICULT LABOUR CAUSED BY DISTENDED FETAL VAGINA.

I AM indebted to Dr. Young (Masselburgh) for permission to publish the following note:

A primipara, aged 21, eight and a half months pregnant, complained of swelling of the legs, and stated that she had not "felt life" for about a fortnight. On examination the abdomen appeared satisfactory and fetal heart sounds were made out; the urine contained 9 parts per 1,000 albumin. Two days later she was confined. The labour was simple as far as the head was concerned, but it seemed impossible to deliver the body on account of the large size of the child's abdomen. However, after using powerful traction, the difficulty was at last overcome, the distended abdomen producing an incomplete tear of the perineum. The child was stillborn. The mother made an uneventful recovery, and the albuminuria rapidly cleared up.

Post-mortem Examination of Fetus.

Unfortunately this had to be carried out very hurriedly a few minutes before the funeral. The anus was imperforate. On opening the abdomen a mass about the size of a child's head presented in the incision; this represented the pelvic organs, which were bound together by adhesions. The peritoneal cavity contained a considerable quantity of clear amber fluid. On incising the protruding mass at least 6 oz. of clear deep amber fluid escaped with a few flakes. The liver, kidneys, and spleen were healthy; the mass of pelvic organs was removed for examination. The specimen was found to consist mainly of a very greatly dilated double vagina, a bicornuate uterus, and the bladder and rectum. The two uterine bodies were distinct, somewhat dilated, and each had a Fallopian tube and ovary attached, the appendages being normal. The two cervixes and vaginae were separated by a septum. The former were not well developed, but were represented by a sort of pocket at the upper part of each vagina, the position of the os being marked by a crescentic "shelf" in each case. The urethra was buried in the septum between the two vaginae, and a narrow passage from the rectum was found running down in the septum; the vaginal walls showed distinct rugae. Unfortunately the external genitals had not been removed with the specimen, but from the fact that the vaginae were so greatly distended with fluid it is reasonable to suppose that they were imperforate.

The case is of interest principally from the rarity of a fetal vagina being so distended as to produce difficulty in parturition, and also in showing completely separate development of each of Müller's ducts. The lack of development of the cervixes is curious, as they are usually developed out of proportion to the body of the uterus in the fetus.

Edinburgh.

SYDNEY B. FAULKNER, M.B., Ch.B. Edin.

AT a meeting of the American National Academy of Science, held at the University of Pennsylvania recently, Dr. Simon Flexner announced that a substitute for salvarsan had been prepared at the Rockefeller Institute. The new drug, which is at present known as "A-189," is an organic arsenical compound which is said to be free from some of the disadvantages of salvarsan, and in particular to be less poisonous. It can also be produced very economically, the cost being about 5 cents a dose.

Reviews.

WOUNDS OF THE SKULL AND BRAIN.

Among the recent additions to the Collection Horizon is a volume¹ dealing with wounds of the skull and brain by MM. CHATELIN and DE MARTEL. It is based on an experience of 5,000 cases treated at the Salpêtrière at Paris, an experience probably quite unique not only in the numbers treated, but also in the facilities for careful examination, diagnosis, and treatment. The authors lay great stress on the minute and accurate examination and record of the wounded man, starting with the exact circumstances in which the wound was received and the first symptoms noticed, followed by a detailed account of the progress of the case and the nervous symptoms presented. After summarizing the signs common to all wounds of the skull, a description is given of those produced by wounds of the frontal lobe, of the Rolandic area, of the temporal, the parietal, and the occipital lobe, and of the cerebellum, and the anatomy of the various structures of the brain is described. Such complications as meningitis, cerebral abscess, and epilepsy are next dealt with, and the effects of the presence of foreign bodies discussed. The chapters dealing with treatment are excellent, and will well repay careful study. The authors hold that urgent operations such as are so often necessary for abdominal wounds are rarely required, and that gunshot injuries of the skull should be moved to a station where they can remain continuously under the care of the surgeon who performs the operation. Local anaesthesia is advocated, the advantages claimed being (1) that the sitting posture, which is the ideal, is practicable in the majority of cases; (2) that haemorrhage is diminished; (3) that post-anaesthetic vomiting is abolished. Anaesthesia is produced by novocain combined with adrenalin. The patient sits in a special chair with a head rest. The authors' method of avoiding haemorrhage is ingenious, and is stated to be effective. Quadrilateral flaps are made, an assistant presses the scalp on one side of the proposed incision vigorously against the bone with the ulnar border of his hand, and the surgeon does the same on the other side. After the incision is made and before the pressure is removed, the external aspect of the wound is seized in special forceps with a T-shaped end capable of grasping about 1 in. of tissue; the same procedure is repeated on the other two sides of the flap; the fourth side, on which, of course, there is no incision, has previously been underlaid with a haemostatic suture, and thus all bleeding is avoided. The authors insist that a craniectomy, to be satisfactory, must be carried out quickly without undue concussion or shaking of the patient's skull, and without any injury to the brain or dura mater. To carry out these principles they make use of several ingenious instruments. No mallet or chisel is employed. They make their bone section from within outwards. First, four small holes, 14 mm. in diameter, are made with a special form of perforator, then a grooved steel elastic band (Marion's protector) is passed from one corner to another, along this a Gigli's saw is guided, and the bone sawn through. This is done on three sides, and the fourth is raised without being actually broken by means of an instrument called *le Brise-base*, which consists of male and female parts fitting into one another, and worked by means of a screw. The female piece ends in a flat portion, which is slipped under the top of the bone flap; the male blade, which terminates in a point, is placed on the skull just above the bone flap. When the screw is turned sufficient force is exerted to break the bone away at the base. The authors insist on the greatest care in avoiding further injury to the brain when removing splinters of bone and pieces of metal. Minute fragments are sometimes best removed, they say, by simple prolonged irrigation with warm physiological serum. Full details of the treatment of all conditions likely to be met with and of the accidents and complications of operation are described. The book can be highly recommended as a most valuable treatise on this particular branch of war surgery. It bears the impress of skilled and practical observers and operators.

¹ *Blessures du Crâne et du Cerveau*. By Ch. Chatelin and De Martel. Paris: Masson et Cie. 1917. (Demy 8vo, pp. 275; with 100 illustrations. 4 francs.)

NEUROLOGY.

At the present time, when the attention of practitioners is continually directed to fresh problems in the diagnosis and treatment of nervous disorders, it is essential that the student of medicine should obtain a thorough grasp of the principles and practice of neurology. The appearance of *A Manual of Nervous Diseases*,² by Dr. IRVING J. SPEAR, is, therefore, particularly opportune. The book, designed for the use of the general practitioner and student, begins by a systematic description of the anatomy and physiology of the nervous system. The section on anatomy is excellent and deserves especial praise, the more so as most writers on nervous diseases are apt to give but scant attention to the subject. The busy practitioner who wishes to obtain an insight into some special condition can hardly be expected to delve into the dusty volumes of his student days to look up a point of anatomy. The author has appreciated this fact and given him the help he needs.

For the proper understanding of the science of neurology three things are necessary: First, a knowledge of structure, that is, anatomy; secondly, ability to correlate pathological signs and symptoms with damage to a particular structure; and, lastly, familiarity with the diseases met with in neurological practice. The author rightly insists on the fundamental importance of anatomy, but we wish that he had seen fit to devote a little more space to the study of function. The few paragraphs on physiology contain scarcely more than may be found in any textbook on that subject. What is wanted, and what is especially valuable to the student, is the translation of physical signs into pathological lesions. We want to be told that spasticity, increased deep reflexes, and extensor plantar response are characteristic of lesion of the pyramidal tract; we would fain know something of the diagnostic significance of diplopia, or of how to distinguish the paralysis of a cranial nerve from lesion of its nucleus. True, a certain amount of information of this nature is given scattered in various sections of the book, but usually only in incidental fashion, and not in a manner calculated to call the student's attention to its importance.

The description of the various diseases of the nervous system is well done, the chapters being short and to the point. The work is eminently practical, theories being left out as far as possible. Diseases of simpler structures, such as peripheral nerves and muscles, are dealt with first, the more complicated disorders of ductless glands and vasomotor system, and the trophic neuroses being left till the end. This arrangement, although in many respects good, occasionally leads to anomalies in classification. For instance, the author includes progressive bulbar paralysis under diseases of the muscular system, while progressive muscular atrophy and amyotrophic lateral sclerosis, which he describes as separate diseases, are placed under the heading of spinal cord. The subjects of hysteria and neurasthenia are ably and fully dealt with, the vexed question of psycho-analysis being treated in a sane and rational manner, and the dangers of this method in inexperienced hands insisted on. A detailed account of treatment is given wherever possible, and should prove of much value to the practitioner.

The publication of a second edition of *Diagnostic Symptoms in Nervous Diseases*³ is proof that the volume holds a place of its own among textbooks of neurology. Dr. HUNT's aim is to give as shortly as possible the salient points and leading symptoms of the principal nervous diseases. This being so, we venture to think that the first chapter, containing over thirty pages of instructions for the examination of a nervous case, is somewhat unnecessarily detailed. For example, with reference to the previous history of the patient, he says: "Begin with the mother's pregnancy, labor, and delivery. Make a careful study of the infancy, the age at which the patient walked, talked, and teethed; the mode of feeding and bringing up

² *A Manual of Nervous Diseases*. By Irving J. Spear, M.D., Professor of Neurology at the University of Maryland, Baltimore. Philadelphia and London: W. B. Saunders Co. 1916. Post 8vo, pp. 650; 172 figures. 12s. 6d. net.

³ *Diagnostic Symptoms in Nervous Diseases*. By Edward Livingston Hunt, M.D., Assistant Professor of Clinical Neurology, College of Physicians and Surgeons, New York City, etc. Second edition revised. Philadelphia and London: W. B. Saunders Co. 1917. (Demy 8vo, pp. 292; 64 figures. 8s. 6d. net.)

the child; the progress of the child at school; then the home life of the individual, together with the bringing up, diseases and incidents of the next twenty years." This is but a small portion of the investigation we are directed to make. The book consists very largely of lists of diseases in which some special symptom occurs. Unfortunately, this method of instruction, useful as it undoubtedly is for examination purposes, is open to the objection that it does not give the student any real insight into the origin and cause of the symptom described, and that often diseases are grouped together which have nothing in common. The author is apt to sacrifice accuracy to brevity. The symptom of dwarfism, for instance, is dismissed in the one sentence: "Dwarfism usually means cretinism." Achondroplasia, which in England, at any rate, is the commoner condition, is not mentioned. Again, we do not think that muscular dystrophy should be grouped as a disease of the spinal cord. These defects are unfortunate, for when the author turns from his lists and tables to a more descriptive style he gives us some really good reading. The chapters on tremors, aphasia, and cerebro spinal fluid are excellent. We wish that he had brought the whole volume up to this level, and so made it a work of scientific value rather than a cram-book for examination candidates. The illustrations are clear and well chosen and are an attractive feature of the book.

ARMY GENERAL HOSPITALS.

LIEUT. COLONEL P. MITCHELL has edited, and partly written, a useful little work on the administration of *Army General Hospital Administration* under active service conditions.⁴ The information which it conveys is based upon the experience of the present war, which has made necessary the revision of much that was thought to be accepted knowledge. While the general principles have largely held good, their practical application has had to be constantly modified under the stimulus of new methods of treatment and new conditions of warfare. The notes compiled by Colonel Mitchell and his colleagues serve a double purpose: they furnish a short guide to the administration and hygiene of a hospital camp, and they indicate to those who are already experts in these matters certain possibilities of improvement upon the present high standard of efficiency.

A critical attitude, when not overdone, is to be welcomed in a work of this kind: the usual fault is reverence for the established order of things. No manual on hospital administration by an officer of the regular army would be likely, for instance, to state bluntly that "the first military reason in determining the rank of a clinical officer should be his fitness from experience to perform specialized duties and not length of service in the army"; nor perhaps would such an author, whatever his private opinion, lay down the proposition that "No medical officer should have duties which can be performed by a N.C.O. or a non-medical officer; nor should medical duties of a commonplace nature, or of only clerical medical value, be performed by medical officers possessing valuable clinical experience—for example, M.O. i.e. of dépôts of medical stores, registrar in a general hospital." But Colonel Mitchell is not deterred by respect for authority from saying such things. The same note of implied criticism is apparent in Major G. H. Colt's suggestive contribution on the organization and equipment of the surgical division. The section on camp sanitation, by Captain Robert Richards, gives an excellent summary of the subject within the small compass of thirty pages; while Major A. W. Falconer's short chapter on the medical division has some sound remarks on the importance of case sheets. Both he and Major Colt protest against frequent changes of medical personnel—always a thorn in the side of administrative officers.

On this subject Colonel Mitchell goes even further: "Junior officers possessing specialized clinical experience," he maintains, "ought not to be reposted from ward duties to regiments or field medical formations, where their clinical value is not exercised, simply because they happen to be young; and if transferred on the plea of urgency, they should be returned as soon as possible." In another chapter he says that general practitioners are relatively of

more value to the civil community than to the army, and ought, therefore, to be the last group to be enlisted in numbers. Even those most disposed to accept the truth of this may be left wondering how Colonel Mitchell would maintain the supply of regimental and field ambulance medical officers in face of the demand.

THE PRINCIPLES OF RATIONAL EDUCATION.

In the reconstruction after the war education will be in the melting-pot, and it is only right that, among other voices, that of the medical profession should be heard. From his ripe experience of Cambridge, Sir Clifford Allbutt expressed his views on the aims and objects of education in the educational supplement of the *Times*, and thereby stimulated Dr. MERCIER to expand an intended magazine article into a small book on *The Principles of Rational Education*.⁵ The main aim of education is to fit the child for his life by the formation of character, by inducing clear thinking and accurate expression, and by imparting a knowledge necessary to action. While freely admitting that, as tested by the ordeal of the war, the character of British manhood and womanhood has generally come out admirably, Dr. Mercier trenchantly condemns our system of education in some of its aspects. He is merciless in his condemnation of the classical routine as a means of teaching English, holding that it is a fallacy to say that it engenders a good literary style, and forcibly insists that the public schools do not furnish boys with any knowledge at all. His criticism is highly destructive, but he is careful to be constructive also, and after a study of the child a reasoned account is given of how he should be progressively taught movements, speech, writing, and be shown first how to do things, and only later to know details. Children should be taught to think, and incidentally John Hunter's "Don't think, try," is converted into "When you have thought, try," and the sound maxim inculcated, "It is no use trying to teach a child anything unless you can interest him in it." The natural tastes and abilities of children should be seriously taken into account in deciding on the course of instruction, and, most important of all, the method of teaching should be reformed. Dr. Mercier writes very strongly because he feels very strongly, and, as it is impossible to make an omelette without breaking eggs, it is unlikely that he will escape hostility from the teaching profession, whom, it must be admitted, he does not go out of his way to conciliate. His conclusions are keen, refreshing, and, if iconoclastic, still essential, true, and wholesome.

NOTES ON BOOKS.

THE Ministry of Munitions has issued a small handbook entitled the *Health of the Munition Worker*.⁶ It is founded upon a series of memoranda issued from time to time during the last two years by the Health of Munition Workers Committee. Sir George Newman, the president of the committee, in a preface to the handbook, says that its purpose is to state in a brief categorical and somewhat dogmatic form the principal steps which must be taken to maintain the health and efficiency of the worker. It is intended to serve as a guide to directors, managers, foremen, and others in authority in munition works, but many of the suggestions it contains have a bearing on problems arising in other industries. It contains a number of photographs showing the costumes for use in particularly dangerous trades, the general appearance of kitchens, storerooms, and serving rooms in canteens, and a works surgery. It also contains a number of plans for canteen buildings and sketches of various fittings, including a set showing a variety of types of seats for use while at work. The appendices contain a list of canteen equipments, an order made last September with regard to the provision of first aid, a copy of the "rules for the use of trinitrotoluene," and some other official information. The book, which is provided with an index as well as a table of contents, will be found very useful for consultation by persons having any responsibility with regard to the health and welfare of munition workers.

⁵ *The Principles of Rational Education*. By Charles A. Mercier, M.D., F.R.C.P., F.R.C.S. London: The Mental Culture Enterprise, 1917. (Cr. 8vo, pp. xi + 87. 2s. 9d. net.)

⁴ *Memoranda on Army General Hospital Administration*. By various authors. Edited by P. Mitchell, M.D., Aberd., Lieut.-Colonel R.A.M.C. (T.F.). London: Baillière, Tindall, and Cox, 1917. (Demy 8vo, pp. 109; 8 illustrations. 5s.)

⁶ *Health of the Munition Worker*. 1917. London: H.M. Stationery Office. (Pp. 158. 1s. 6d. net.)

The British Red Cross Society has issued a small *Manual of Splints and Appliances for the Treatment of Bone and Joint Injuries*,⁷ prepared for the use of the United States army, and formally approved last September. It was compiled by a board of medical officers. It is primarily intended to enumerate, describe, and illustrate certain simple types of apparatus all very generally applicable, and to encourage standardization. In this matter of the provision of splints the administration is in a dilemma; on the one hand it would be very undesirable to discourage ingenuity in the devising of improvements in splints, and on the other the multiplication of types of splints causes serious difficulties in supply. In an introductory note, written for the edition issued by the British Red Cross Society, Surgeon-General Sir George Makins says that "no advance or new procedure in military surgery has contributed in a greater degree to the well-being, comfort in transport, and general success in results attained, than the extended adoption of splints of the H. O. Thomas type," and our readers will remember a paper by Major Osgood, a member of the committee who prepared this handbook, published in the JOURNAL of October 13th, 1917, in which he described some adaptations of the Thomas splints to special conditions, remarkable for their ingenuity and simplicity. The committee expresses the belief that "with the three types of wire-ring traction and counter-pressure fixation splints embodying the Thomas principle, the Jones 'cock-up' 'crab' wrist splint, the long interrupted Liston splint with adjustable footpiece, an anterior thigh and leg splint, Hodgen type, the Cabot posterior wire splint, the wire-ladder splint material, light splint wood, and plaster-of-Paris bandages and Bradford frames, treatment of all bone and joint battle casualties may be efficiently carried out at the front, and if necessary in base hospitals."

A portfolio containing a description, copiously illustrated, of No. 7 (Queen's) Canadian General Hospital has been issued. The hospital has had the support not only of the Red Cross Society in general but of the branch in Kingston, Ontario, and the Queen's University in particular. The offer to raise it, made in November, 1914, by Colonel Etherington, C.M.G., at present in command of it, was not at once accepted, but at the end of March, 1915, the medical faculty at Queen's University resolved to give its support and assistance, and students from all faculties offered themselves. The unit left Canada in May, 1915, with an establishment sufficient to provide for 200 patients. Shortly after arriving in England the accommodation was doubled, and the necessary additional personnel was raised in Kingston, and joined the unit in July. On August 14th a 600-bed hospital was opened at Cairo, and the additional personnel was again recruited in Kingston. At the close of the Gallipoli campaign the hospital moved to France and conducted a hospital of 1,040 beds under canvas during the Somme offensive. In November, 1917, the hospital, on another site in France, provided accommodation for 2,300 patients, and had apparently come to the end of its travels.

The essay on *The Psychology of War*,⁸ by a lecturer on medical psychology at Cornell University, was mainly written in 1916, but there is a short chapter on "America at War." Dr. MACCURDY is convinced that peace will be accelerated by a more widespread understanding of the psychology of war, which is compared to insanity and, like it, occurs explosively after periods of quiet. Freud and Trotter are probably the only psychologists whose hypotheses are not essentially tautological, and accordingly psycho-analysis and the herd instinct only need serious consideration. Freud considers that civilization has repressed man's primitive instincts, which are constantly striving for an outlet in war; whereas, according to Trotter, man is instinctively a herd animal, and when his gregariousness becomes aggressive war is imminent. The author combines these two hypotheses to explain war: as a result of the herd instinct, which makes man accept the opinions of those immediately around him—herd or mob suggestion—the actions of his group only seem right, and antagonism to the other groups occurs; and then man's primitive instincts assert themselves. Education is, he thinks, the remedy for war, just as preventive psychology is for insanity; instincts act unconsciously, but if a man is so educated as to know himself and recognizes and controls his instincts, there is hope that in the future war may be prevented.

The fourth edition of Professor SAYRE'S *Manual of Organic Materia Medica and Pharmacognosy*,⁹ a work that has been used in America for nearly thirty years, is a handsome and well arranged volume in which the materia medica of the ninth revision of the United States Pharmacopoeia is discussed from what may be described as primarily a botanical point of view. The volume is divided into four parts. The first of these gives a classification and conspectus of the various drugs employed, official and unofficial; the second, extending to 410 pages, gives a description of these drugs, and is illustrated with many botanical pictures; and the third contains an account of the insects injurious to drugs, a matter of no little importance to the druggist whether wholesale or retail. The fourth part describes the methods of recognizing powdered drugs, largely by the use of the microscope.

⁹ *A Manual of Organic Materia Medica and Pharmacognosy*. By Lucius E. Sayre, B.S., Ph.D. Fourth edition (revised). Philadelphia: P. Blakiston's Son and Co. 1917. (Med. 8vo, pp. xviii+606; 302 figures, 4.50 dollars net.)

PNEUMONIA AND ITS SERUM TREATMENT.

For some years the special study of pneumonia, which has been in progress at the hospital of the Rockefeller Institute, New York, under the direction of Dr. Rufus Cole, has added much to knowledge and has inspired work on the same lines elsewhere in the United States. A number of reports on the subject have appeared recently and deserve attention.

Analysis of 454 cases of lobar pneumonia in the Rockefeller Hospital during the past five years is of interest in connexion with the types of pneumococci which, as will be seen later, have an important bearing on the treatment by antipneumococcal serum; Type I was responsible for 33 per cent., Type II for 29, Type III for 13, Type IV for 20, and atypical forms of Type II for the small remainder (Stillman). At the Johns Hopkins Hospital, Baltimore, 54 cases of lobar pneumonia, investigated by Clough,¹ between February, 1915, and September, 1916, showed that the percentage incidence of the types of pneumococci agreed very closely with those at the Rockefeller Hospital and elsewhere in America, except for the low percentage of Type II and the correspondingly high percentage of atypical Type II strains, which have only been recognized during the past two years. Incidentally it may be noted that the strain of pneumococcus most frequently found in the pneumonia among the blacks in the Rand, South Africa, appears to belong to Type IV, and that F. S. Lister,² who independently and practically simultaneously (1913) with Dochez and Gillespie in America separated out four types of pneumococci, has now described four more types of pneumococci in South Africa in addition to those of the American observers.

With regard to the pneumococci found in the mouths of 50 per cent. or more of normal persons, Stillman shows that Type IV predominates, that Type III is frequent, that atypical forms of Type II are occasionally present, and that Types I and II are rare unless the carriers have been in contact with cases of pneumonia due to these types; thus among 184 normal persons intimately associated with Type I or II infections 11 per cent. carried pneumococci of these types, whereas among 297 persons without any history of contact, pneumococci of Types I and II were present in 0.8 per cent. only.

The occurrence of pneumococci in the dust of houses, though of significance in the incidence of the disease, has hitherto attracted little attention. From the dust of rooms inhabited by patients or carriers of Types I or II pneumococci of the same type may be recovered, whereas in the dust of rooms not so inhabited the predominant pneumococcus is Type IV. Types III, IIb and IIc being also present, whereas Types I and II are very rare. These data justify the conclusion that infection with Types I and II depend upon contact with a case or carrier of these types, the contact being either direct or indirect, that is to say, air-borne from dust.

An intensive study of blood cultures has been carried out at the Johns Hopkins Hospital by Sutton and Sevier,⁴ who made daily cultures in 65 cases of pneumonia from the day of admission until the rectal temperature fell below 100° F. A striking correspondence was thus brought out between the percentages of the positive blood cultures and of the mortality; in cases of pneumonia due to Type I the percentage of positive blood cultures was 45.8, and that of

⁷ Published for the British Red Cross Society. London: Hodder and Stoughton. Oxford University Press: Henry Frowde. (2s. 6d. net.)

⁸ *The Psychology of War*. By John T. MacCurdy, Lecturer on Medical Psychology, Cornell University Medical School, New York. London: William Heinemann. 1917. (Cr. 8vo, pp. ix+68. 2s. 6d. net.)

deaths 41.7, and in pneumonia due to Type IV both percentages worked out at 18.2. Among the cases with persistently negative blood cultures there were three fatal cases only, and two of these had very extensive consolidation. From observation of eleven cases of pneumonia (Type I) treated by antipneumococcal serum at the Johns Hopkins Hospital, Bloomfield⁸ found that the serum prevents the occurrence of haemic infection, and that it sterilizes the blood when septicaemia has already arisen.

In an investigation into acidosis and acid excretion, W. W. Palmer⁹ showed that in many severe cases of pneumonia the urine contains a large quantity of an organic acid, the nature and significance of which are being made the subject of further research, but that acidosis as determined by the combined CO₂ in the plasma is seldom, if ever, grave.

In a paper containing several points of great interest Dochez and Avery⁷ find that the pneumococcus, which is not known to produce a soluble toxin, and the pathogenic effects of which are supposed to be due to an endotoxin, or to split protein products liberated on its death and disintegration, during its active growth throws out into the blood of experimental animals and pneumonic patients a soluble substance, possibly analogous to Bail's agglutinins. This soluble substance, which the authors are careful not to call a toxin, as they have not as yet been able to prove with certainty that it is responsible for the intoxication accompanying pneumonia, gives a specific precipitin reaction with the antipneumococcal serum corresponding in type to that of the pneumococcus infecting the patient. In cases persistently excreting the precipitable soluble substance in the urine resolution of the pneumonia is delayed, and its amount serves as an index of the severity of the infection; cases with large amounts prove fatal, whereas most of the cases that fail to show it recover. This precipitin test is not only of considerable prognostic importance, but it provides a rapid diagnosis of the type of pneumococcus responsible for the patient's pneumonia. Cole,¹⁰ writing, like Dochez and Avery, from the Rockefeller Hospital, but without making any reference to their conclusions, shows that in pneumococcal infection soluble substances (virulin or antiphagin), found especially in pleuritic exudates but also in the blood, may fix and so remove from the blood the antibodies contained in antipneumococcal serum injected intravenously. In such cases the serum becomes effective only when the soluble substances have been neutralized, and hence in severely infected patients the serum should be injected early and the initial dose should be large. Agglutinin curves, which appear to be an index of any other specific antibodies in the blood, before and after the intravenous administration of serum may explain why in some instances antipneumococcal serum fails to do good. Other and most important limitations of the antipneumococcal serum treatment are (1) that, as the types of pneumococci have in general a high degree of specificity, a homologous serum is necessary; and (2) that while the immune serum against Type I is of great therapeutic value, the serums corresponding to Type II and others have as yet proved ineffective. The use of antipneumococcal serum should, therefore, be confined to cases of pneumococcal infection proved to be due to Type I. Cole and Moore⁹ describe in detail the method of manufacturing this serum. Blake's¹⁰ observations throw some light on the mode of action of antipneumococcal serum. As the serum retards the growth and metabolic activities of the corresponding type of pneumococcus, it has been thought that it does so in virtue of an antizymotic (or antiblastic) effect on the surface of the bacteria. But Blake shows that the inhibitory and agglutinating powers run parallel, and that with the removal of the agglutinins the inhibitory influence of the serum disappears. The inhibition of the metabolic activity of pneumococci, therefore, appears to be due to their agglutination and consequent inability to grow in intimate contact with the whole medium.

In a number of instances intravenous injection of antipneumococcal serum was followed by a sharp reaction and chill, after which the temperature fell, but rose again; this sequence might be repeated after a further injection. Dochez¹¹ refers to 65 cases of pneumonia due to pneumococcus Type I treated by the homologous serum with a mortality of 7.5 per cent., or a reduction of 17.5 per cent. as compared with the mortality of 25 per cent. in cases of

pneumonia (Type I) treated on ordinary lines. Serum disease is frequent after this treatment; it occurred in 7 out of Bloomfield's 9 cases that lived long enough, was severe in 5, and in a case that received 1,100 c.cm. a well-marked reaction persisted without intermission for thirty-seven days, in another case for twenty, and in a third for fourteen days. In two cases alarming anaphylactic shock occurred immediately after injection, although no evidence of hypersensitiveness had been given by the preliminary desensitizing injection. Among fifteen patients given antipneumococcal serum at the Peter Bent Brigham Hospital by Alexander¹² three were known to be subject to horse asthma and had asthmatic symptoms after the serum but did not manifest serum disease, even after 350 c.cm., whereas the non-asthmatic patients nearly always showed serum reactions.

A DIETARY WITHIN THE RATIONS.

THE actual construction of diets conforming to the Food Controller's wishes and at the same time providing adequate energy at prices within the means of working class families is extremely difficult. The accompanying table is a suggestion. The amounts of rationed articles are based upon the voluntary ration for an adult man on ordinary industrial work. The diet provides 3,258 calories with 88 grams of protein and would cost at controlled maximum retail prices (tea at 4s. per lb.) 1s. 1½d. daily.

Daily Amounts.	Calories.	Prices (in pence).
Breakfast:		
Bread 6 oz.	441	0.84
Margarine 4 oz.	56	0.19
Oatmeal 1 oz.	116	0.31
Milk 2 pint	51	0.50
Sugar 4 oz.	57	0.19
Tea 4 oz.	—	0.37 — 2.40
Dinner:		
Bread 2 oz.	147	0.28
Meat 3 oz.	195	3.04
Margarine 3 oz.	111	0.38
Potatoes 1½ lb.	641	1.50
Rice or flour 1 oz.	103	0.16
Jam or syrup 2 oz.	30 — 1,227	0.28 — 5.64
High tea and supper:		
Bread 8 oz.	688	1.13
Meat 1½ oz.	97	1.52
Margarine 3 oz.	167	0.57
Potatoes 1 lb.	320	0.75
Milk 2 pint	51	0.50
Sugar 4 oz.	67	0.19
Jam 2 oz.	30	0.28
Tea 4 oz.	—	0.37 — 5.31
Totals	3,258	13.35

This diet as it stands is hardly sufficient, and no provision is made for green vegetables. If a margin of sixpence daily is allowed to cover the cost of cabbages and other greens and the addition of small quantities of fish, more jam, eggs, and cheese, when these articles are available, it would seem that 1s. 7½d. a day is sufficient to cover the cost of food alone. It is hard to see how the cost can be reduced further save by the substitution of more potatoes.

BRIGADE-SURGEON JAMES DAVIDSON of Aberdeen, who died on July 26th, 1917, left personal property of the value of £49,763. He left £100 each to the Aberdeen Royal Infirmary and the Aberdeen Sick Children's Hospital, and £50 each to the Maternity Hospital, Aberdeen, and the Royal Medical Benevolent Fund, London.

British Medical Journal.

SATURDAY, JANUARY 12TH, 1918.

THE INDIAN MEDICAL SERVICE.

THE visit of the Secretary of State for India to that country, which is, we believe, an unprecedented incident, has been generally accepted as evidence that the British Government has come to the opinion that the system of administration in India needs overhauling. During the past generation or two it has become more and more centralized, owing partly to greater rapidity of communication so that the authority of a central department is more easily exercised, but partly also to the growth of the power of the central bureaucracy. These two influences have combined to stereotype methods and discourage originality.

The old idea, not peculiar to this country or to India, was that in its policy a national government need concern itself only with such matters as taxation and expenditure, the franchise, and the prevention and making of war. But the public at home now requires a cabinet to have a policy of social reform, and is beginning to recognize that a part of this must be a well-informed and comprehensive health policy. Consequently one of the first works of reconstruction, to be carried through if possible even before the end of the war, is the establishment of a Ministry of Health, whose function it will be to stimulate the study of large general principles and to direct and encourage local efforts to apply them in detail. In India there has been no settled health policy, owing, we take it, to the circumstance that the Indian bureaucracy, able as so many of its individual members are, has not reached the stage of political development when this obligation of good government is recognized.

Two recent instances of the unfortunate result of the absence in India of a well-informed and comprehensive health policy are afforded by the failure to control the outbreak of plague, and the story of the early stages of the Mesopotamia campaign. In neither case did the Government of India at the outset call in experts to ascertain the facts; in both it was content, at first, to work by rule of thumb, and only sought the knowledge that would have prevented the mischief after part of the mischief was done. The patent failure of bureaucratic methods to stay the plague had this good effect at least, that it put into the hands of the late Sir Pardey Lukis a lever to move the Government of India to give practical recognition to the importance of scientific research in epidemiology and pathology as implements of good government. No man could have used his opportunity more wisely, but he would have been the first to admit that his achievement, great as in the circumstances it was, was only a beginning, though a promising beginning.

The Indian Medical Service, and the two Government medical departments in India which are rather unhappily named subordinate, have suffered many things at the hands of the Indian bureaucracy. We propose now only to deal with the premier service, reserving what we have to say of the two departments for another occasion. The Indian Medical Service has a splendid record in clinical medicine and surgery, and in research, but it has fallen

on such evil times that its sincerest friends are tempted to despair of it. Before Mr. Montagu started for India he had been asked to receive a deputation to speak on behalf of the British Medical Association. There seems to have been some delay in bringing the request to his notice, and there was then no time for him to arrange the interview before he started. It has been considered advisable to send to him a memorandum, which is published in the SUPPLEMENT this week, on certain defects in the constitution of the Indian Medical Service, in anticipation of the interview which is to take place on his return to this country. The memorandum is not intended to deal with every detail which must be adjusted by the Secretary of State and the Government of India if the Indian Medical Service is to be put on a satisfactory footing to enable it to do the best possible for the peoples of India, but it is believed to touch all these matters of principle by which details must be determined. The preamble sets out some truisms which it would seem are not understood by the secretariats at home or in India. The first three sections of the body of the memorandum are concerned with the position the advisers of the Secretary of State, of the Government of India, and of the Provincial Governments on medical and hygienic research and administration should hold in order to ensure that expert advice shall always be available to the governments in framing a sound health policy and in carrying it out in practice.

The remainder of the memorandum deals broadly with education and recruitment and with emoluments. If Great Britain is to provide an Indian Medical Service at all it must attract the best. Less now than ever does India want the second-rate. The attraction by which the Indian Medical Service drew the right sort of young medical men was that it offered a career where the recompense for the hard work which must go to the acquisition of skill would be found in the immense opportunities for the exercise of that skill, in the respect of the peoples benefited by it, in the recognition of the value of such work by the Government, and, finally, in the winning of the pecuniary reward which justly attends the successful practice of a learned profession. The glory of the Indian Medical Service has been the number of men it has produced eminent in clinical medicine and surgery, including the various specialities, particularly, perhaps, ophthalmology, and in scientific research. A wise Government would do everything possible to foster their succession. That the contrary policy is being pursued by the ruling class in India is to be attributed to want of imagination due to the causes indicated at the beginning of this article, and in part, it is to be feared, to hierarchical exclusiveness and an unworthy jealousy. We trust to Mr. Montagu to put the matter right.

THE PROBLEM OF CONGENITAL SYPHILIS.

DR. AMAND ROUTH, in his recent address on antenatal syphilis, of which we print an abstract this week, propounded an interesting explanation of anomalies found in certain syphilitic children and their mothers in respect of negative Wassermann reactions, and the absence of spirochaetes in the tissues. He suggests that the chorionic ferments have a destructive action upon the infective agent, tending to protect the mother and child from infection during pregnancy, by breaking up the spirochaete into granules which are biologically less active than the mature organism.

This view, if confirmed, would account for the fact that congenital syphilis is so often not apparent at birth, and sometimes even remains quiescent until puberty, while the mother may show a like latency of symptoms.

But apart from the interesting field for speculation and research which he opens out, Dr. Routh's address comes as a timely reminder of the havoc due to congenital syphilis. He estimates that 25 per cent. of stillbirths and abortions in the urban centres of this country are probably due to syphilis. When to such figures are added the number of children dying from marasmus and other deadly manifestations of inherited syphilis, the wastage of life due to this poison is seen in something like its true perspective. Evil as are the effects of acquired syphilis in the adult, those of congenital syphilis are still more disastrous. And this is not to be wondered at, since throughout prenatal existence and early life the tissues invaded by the syphilitic virus are in course of active development, with a correspondingly greater susceptibility to grave and lasting damage. The congenital form of syphilis is constitutional from the outset, and exerts a profound influence for ill upon nutrition, growth, and vitality. After an investigation of 516 cases of congenital syphilis Hoehsinger came to the conclusion that only about 25 per cent. of the infants thus infected grew up into comparatively normal adults.¹ There is no reason to suppose that that was an overstatement of the position a few years ago; though we may hope that early and adequate specific treatment of the mother throughout pregnancy and of the child in the first years of life will before long lead to better results. Nevertheless, a more recent report by Veeder² upon 331 pregnancies in 100 syphilitic families, indicates that among the 161 surviving children only 33 were free from infection at the time of the investigation.

In recent years the movement of medical opinion has been towards an increasing recognition of the serious nature of congenital syphilis in the light of modern diagnostic methods. Thirty years ago so high an authority as Jonathan Hutchinson wrote: "In hospital practice and amongst the poor the mortality from syphilis in infants is large. This, however, is to be explained by the disadvantageous conditions as regards feeding and treatment under which the infants are placed rather than by the severity of the disease itself. Amongst the richer classes the malady is, I think, rarely fatal." This, of course, was written before the discovery of the spirochaete and the introduction of the Wassermann test; and Sir Jonathan Hutchinson happily lived long enough to revise in the light of new knowledge a number of opinions formed when he was ploughing a lonely furrow.

The national campaign against venereal disease has made considerable progress during the past year. The Act now in force prohibits treatment by unqualified persons, and local schemes for diagnosis and treatment have been set up in an increasing number of districts; while the educational work of the National Council for Combating Venereal Diseases continues to supplement municipal efforts. We may here mention, as of particular interest in relation to the problem of congenital syphilis, the venereal centre for pregnant women which the Guardians of the City of London Union have established at Thavies Inn, under the charge of Dr. John Adams. The results of this experiment will be watched with interest, for the grouping together of in-patients for observation and treatment may perhaps lead in time to the

drawing up of therapeutic rules applicable to such cases generally. In the Dominions also the need for action has been recognized. Thus, in Australia, the State of Victoria, under the powers conferred by the Venereal Diseases Act, 1916, has issued drastic regulations making it obligatory upon every person suffering from, or suspecting that he is suffering from, venereal disease to seek qualified advice, to follow the instructions given, and to remain under treatment until he has received a certificate of cure; while the parents or guardians of infected children are under a similar obligation in respect of their charges.

It is clear that such measures, and, indeed, all organized efforts for checking venereal disease, will be of little avail unless medical students are trained in the modern technique of diagnosis and treatment. This was recognized by the Royal Commission on Venereal Diseases, which recorded its conviction that every medical student ought to receive adequate practical instruction, and that his knowledge of venereal disease ought to be systematically tested at the final examination. Up to the present, however, as Dr. David Watson points out in a paper which we publish this week, the General Medical Council has taken no steps to enforce compulsory teaching of either venereal diseases or of the germane subject dermatology. Dr. Watson puts the matter in a concrete form by describing the venereal disease clinic of which he is in charge, and its course of teaching. His sketch should prove helpful and suggestive to the authorities of other medical schools which have not as yet provided their students with special instruction in this most necessary branch of medical practice.

THERAPEUTIC IMPORTANCE OF BACTERIAL STRAINS.

WE publish elsewhere in this issue an analysis of recent American researches into the bacteriology and serum treatment of pneumonia, which, in spite of the mass of rather technical details it contains, will well repay the study of all engaged in the practice of medicine whether as general practitioner or physician. Pneumonia—raised by Osler to the rank of "captain of the men of death," the title conferred on consumption by John Bunyan—is as dreadful a disease for adults as diphtheria used to be for children. It knocks a man down in the prime of health and life, inflicting a blow which, when not fatal, as it so often is, cripples him for months. Bacteriology has robbed diphtheria of many of its terrors, but hitherto has done little for the other disease. The well directed researches carried on for several years past at the Hospital of the Rockefeller Institute and more recently at the Johns Hopkins Hospital, have given a clue which, when followed up, may be expected to afford most important practical results.

It must be admitted that the doctrine of strains of pathogenic organisms introduces a complexity into the practical application of pathological bacteriology that to the plain man may well seem bewildering. But it would be useless to revile the bacteriologists, for that is to quarrel with the facts of nature: and we should rather examine the new facts in order to see if thereby we may extract some explanation of past failure and some hope of future success.

Lobar pneumonia apparently consists of infection by strains of pneumococci which are distinct from one another as regards their serological reactions; and from the point of view of serum treatment pneumonia due to pneumococcus Type I is a different condition

¹ Marshall: *Syphilology and Venereal Disease*.

² *American Journal of Medical Sciences*, 1916, ciii.

from pneumonia due to pneumococcus Type II. It follows that any reasonable certainty of successfully treating pneumonia by antipneumococcic serum depends on the bacteriological diagnosis of the type of pneumococcus present; if it is Type I, the corresponding or homologous serum should do good, but unfortunately this is all that can be said at present, for the antipneumococcic serum for Type II is ineffectual, and the serum homologous to Type I has no effect in pneumonia due to Type II. This example emphasizes what every medical man should, and probably does, know—namely, that in the employment of serums and vaccines it is important, if not essential, to employ one corresponding to the strain of the causal organism. With the advance of bacteriological knowledge the existence of different species and subspecies of organisms formerly regarded as one species has been established. Thus the original *Bacillus typhosus* was shown to have included the *B. paratyphosus* A and B, and the diseases due to these three organisms are now universally known by the names of their causal organisms. This separation, recognized for some years, carries with it the practical application that to protect against enteric fever—the clinical name covering these three diseases—a vaccine of typhoid, paratyphoid A and B bacilli, or T.A.B. for short, must be employed. Similarly, bacillary dysentery may be due to several strains of *Bacillus dysenteriae*, of which the Shiga and Flexner types are the best known, and in practice a multivalent serum containing antibodies for these organisms is often employed.

In addition to the separation of bacteria by their cultural and fermentative characters into species, a further distinction into subspecies or strains can be effected by their serological reactions, as has been shown in the case of pneumococci. But much remains to be learnt as to the fixity of the strains thus isolated and of the practical deductions to be drawn with regard to specific treatment. Thus many strains of the *Bacillus typhosus* have been isolated, and S. B. Hooker has urged that antityphoid vaccine should be multivalent—that is, made from several strains—and yet the ordinary antityphoid vaccine made from a single strain appears to be successful. A great deal has been written about the different strains of the meningococcus; Mervyn Gordon has isolated four types, and serums corresponding to them have been manufactured; and F. W. Andrewes has recently put forward the view that the meningococcus, which is a single definite species recognizable by cultural tests, is divisible into two main types owing to its protein containing two antigens which vary in their amounts. It further appears that the occurrence of strains may to some extent depend on their environment—for example, old typhoid cultures contain different strains from young typhoid cultures, and during epidemics virulent strains of meningococci may arise. With our present experience the best results appear to have been obtained by the use of Flexner's antimeningitis serum, which contains antibodies for thirty-two strains of meningococci.

The practical conclusion is that unless the particular strain of organism present can be determined and its corresponding serum at once be given, it is better—on the principle of a shot gun, in virtue of its diffusion, being more effective than a rifle—to give a multivalent serum than a univalent serum or a serum of unknown origin. In the case of vaccines, an autogenous vaccine, which can be obtained in a few days, is obviously always preferable to a stock vaccine, which may or may not hit the mark. But a serum corresponding to the infecting organism, unless already

available, may take so long to manufacture that its use is possible only in chronic diseases, and in such cases a multivalent serum or a mixture of serums should be employed.

GUNSHOT FRACTURES OF THE FEMUR.

IN the address on the orthopaedic outlook in military surgery, which is published this week, Sir Robert Jones gives fuller expression than in any previous utterance to the great principle that there are two aspects of military orthopaedics—the preventive and the corrective. He illustrated his point by various instances, but that which will probably appeal most to surgeons, both abroad and at home, who are responsible for the treatment of the wounded at the present time, is that afforded by gunshot wounds of the femur. This subject has been actively engaging attention for some time, and a general understanding seems to have been reached that improvements were possible in the treatment of these injuries, so distressing at the time, and so apt to be disabling in their after-effects. They test the skill of the surgeon, the devotion and patience of the nurse, and the organizing power of the administrative officer as perhaps no other class of injury does. It is no exaggeration to say, as he says, that they are the tragedy of the war, not only because they produce many deaths, often after much suffering, but also because shortening and other deformities so frequently ensue, leaving a man incapable of following any but a sedentary occupation. Bitter complaints have been received from abroad of the want of continuity of treatment in this country, while experience here has forced the conclusion that though from certain hospitals abroad cases have arrived most admirably fixed, from others they reach this country in a state leaving much to be desired. Sir Robert Jones says that the mortality has been far too high, and the number of cases showing four or five inches shortening, with every variety of deflection, far too numerous. The remedy, he says, is to put the treatment of these fractures in the hands of specially trained surgeons in special hospitals. There should be one large hospital reserved for them at each base, officered by specially trained surgeons with a mechanical aptitude, prepared to devote themselves to the work, and assured of security of tenure. In addition there should be an inspector of fractures acting in conjunction with the consulting surgeons of the various areas. Moreover, one of these hospitals could be used as an educational centre to which young surgeons could be sent as opportunity occurred. Here again we have the idea of the "team" arising. Sir Robert Jones says that a trained surgeon, an orderly, and a sister would do more rapid and efficient work together than could be done by half a dozen most excellent surgeons not possessing the special experience and trained assistance. He believes that such a training school would in a short time supply regimental aid posts and casualty clearing stations with teams of surgeons and orderlies taught to fix these fractures efficiently and rapidly. The two fundamental principles are efficient fixation in correct alignment at the earliest possible moment, and continuity of treatment. The importance of early fixation, even in the regimental aid posts, seems now to be generally acknowledged. Thomas's splint, which is supplied to the regimental aid posts in some divisions, should, it is urged, be supplied in every division; it can be readily applied over the trousers, and extension made by a pull on the boot, the whole process being accomplished so rapidly that twenty or thirty cases can be dealt with in an hour by a trained team of orderlies. When the man reaches the casualty clearing station he is, we understand, taken to the operating theatre with this splint, trouser and boot still in position, so that the surgeon only begins his examination and treatment of the wound after the patient has been

anaesthetized. It is obvious that this method must contribute to diminish shock, which is the common cause of early death. It is understood that the plan suggested has, at any rate in its main features, now been adopted at the Western front; with regard to the continuity of treatment at home, an Army Council instruction has been issued directing that all fractures of the femur shall be sent on their arrival in this country to orthopaedic centres, or, if these centres are full, to specially selected hospitals. The difficulties with which the surgeons abroad have to contend are acknowledged, and also that they have shown greater initiative than has been displayed at home, but it seems clear that an organization on the lines indicated, administered in a spirit of cordial co-operation, may be expected to have a very beneficial effect on the death-rate, on the sufferings of the individual patients, and finally, on the number of crippled men who are discharged from the army to civil life.

A GAS GANGRENE ANTITOXIC SERUM.

A DEMONSTRATION of an antitoxic serum for the prevention and treatment of gas gangrene was given by Major Carroll G. Bull, U.S.M.C., at the Royal Army Medical College on January 8th, on the invitation of the commandant, Surgeon-General Sir David Bruce, K.C.B. Major Bull's experiments, which were begun in America and are now being continued in this country, have been made with *Bacillus welchii*, which appears to be the organism chiefly concerned in the production of gas gangrene. Cultivations were started from cases occurring in the United States and on the Western front, and also from saprophytic sources, and care was taken to establish the identity of the organism.¹ Its growth in culture is attended by the production of acid, and one explanation that has been offered of the effects produced clinically is that the acid liberates proteolytic ferments; another explanation is that the production of gas leads to the introduction of toxic proteins into the general system; a third is that the process known as gas gangrene is capable of spreading only after the death of the tissues involved. Major Bull, however, has produced strong evidence that the pathological process is produced by a bacterial toxin. He has obtained such a toxin in cultures of twenty-four hours. This toxin, when injected into animals (pigeons and guinea-pigs), produces local oedema and necrosis, and a general effect characterized by haemolysis and degeneration of the red cells, which, in the kidneys, for instance, choke the tubules. An experimental inoculation of the toxin in animals was found to lead to the production of antibodies. The culture medium used was beef broth with 0.2 or 0.3 per cent. glucose, to which fragments of fresh muscle were added at the time of incubation. After eighteen to twenty-four hours the tubes were centrifuged, and the fluid, subsequently passed through a suitable filter, was bacteria-free. The toxin used was so powerful that 2 c.cm. of the fluid would kill a horse after producing local lesions; the potency of the filtrates declined when the period of incubation was prolonged beyond twenty-four hours. For the production of an antitoxic serum a dose of 1 c.cm. was used in a horse, producing a reaction which had subsided in about four days, when the injection was repeated. It was found that the toxin could be exactly neutralized by the antitoxin *in vitro*, so that injection produced no effect. After gas gangrene has been set up experimentally by inoculation with a culture a suitable dose of antitoxin will neutralize the toxin in the tissues, thus enabling them to check the further growth of the organism. Experiments on guinea-pigs showed that preventive injection of antitoxin will prevent infection developing when the active organism is subsequently inoculated, and that the

progress of an infection already started could be arrested by the injection of antitoxin after marked local lesions and general symptoms had developed; a case was related in which a boy suffered a severe injury of the forearm, followed by gas gangrene with very marked constitutional symptoms. The injection of a dose of antitoxin caused immediate improvement in the general symptoms, the temperature falling from 105° to 101°, and the pulse, which had been uncountable, improving to a corresponding extent. The local process was checked and amputation was successfully performed. Major Bull concluded by saying that he believed the evidence to be sufficient to justify the use of this antitoxin in man as a means of cure, and that in the severest cases so much general and local improvement would be brought about that an operation could be undertaken without fear of local extension. At the present time six horses have been immunized at the Rockefeller Institute for the purpose of producing gas gangrene antitoxic serum, and experiments of the same nature have been begun in this country; but, as Major Bull pointed out, if the serum is to be used as a preventive or curative agent on the Western front, it must be produced either here or in France on a large scale.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE position of this Fund was fully set out in the balance sheet which, accompanied by a certificate of the chartered accountant and auditors, was appended to the appeal published in the JOURNAL of December 29th, 1917, p. 863. The Fund was started at the end of 1914, when the deplorable facts with regard to German rapacity and brutality in Belgium first became known in this country. It was started in response to the appeal brought to this country by representatives of the medical profession in Belgium who had been deprived of their means of living, denuded of the implements of their practice, and who had, like the pharmacists, often had to see their houses destroyed. By the first week in February, 1915, over £5,000 was received, and by the end of the first year of working over £18,000 had reached the treasurer's hands. Further contributions and the proceeds of judicious temporary investment of the moneys in hand raised the total by the end of the second year's working to £20,000. The expenses of administration down to the present time have been £62 only, owing to the fact that all services have been given gratuitously. A sum of £800 was transmitted monthly to Belgium during 1917, and the Fund has now been reduced to less than £1,500. A second appeal is therefore now made to the medical and pharmaceutical professions in this country to come to the assistance of their much-tried brethren in Belgium. That the need is great is known not only from general statements recently published with regard to the situation in Belgium—which has grown worse instead of better—but also from specific information supplied by Mr. W. B. Poland, director in Europe of the Commission for Relief in Belgium. Writing on November 20th, 1917, to the Treasurer of the Fund (Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W.1), he said that if the supporters of the Fund knew how much actual suffering they had allayed, and how much potential, moral, and physical suffering they had prevented, they would not cease to continue their support, many as are the claims now made upon them. Mr. Poland quoted from a letter written recently by a Belgian still in that country that "the misery has become terrible and increases every day. It pursues us wherever we go." But Mr. Poland's letter ought to be read in full (page 864). It should be added that the monthly contributions are paid to a committee of members of the medical and pharmaceutical professions in Belgium, and the committee in this country has good reason to know that the Belgian committee is extremely prudent and careful in the distribution of the moneys which reach it. The response to the appeal

¹ Two papers on the subject, by Major Bull and Ida W. Pritchett, will be found in the *Journal of Experimental Medicine*, 1917, xxvi p. 119 and p. 857. From the later paper it appears that twenty-seven strains of *B. welchii* from widely different sources had been studied, and were found all to produce a toxin in common.

made two years ago was so spontaneous and liberal that there seems every reason to hope that the members of the medical profession in this country will again give liberally in spite of the fact that this is only one of the many calls upon their benevolence. It can only be said in conclusion that if the response is not liberal and prompt, the committee of the Fund in this country will be compelled at once greatly to diminish, and before long wholly to suspend, the monthly payments to the committee in Belgium. We publish at page 71 a preliminary list; lists of further subscriptions will be published from time to time.

A NEW PORTABLE X-RAY TUBE.

A new development in x-ray tube construction, which was compared by one speaker to the advent of the kodak in photography, was brought before the Röntgen Society on January 1st. Like the hot-cathode tube which was introduced three or four years ago, this new arrival is also associated with the name of Mr. W. D. Coolidge and his Schenectady laboratories. It has been developed in America specifically for use with portable x-ray outfits in the United States army, but its characteristics are such that it may supplant ultimately the earlier types of hot-cathode tubes for all radiographic work. This new tube is based on the same essential principles as the older Coolidge, but its bulb is no more than $3\frac{3}{4}$ in. in diameter. The target, which receives the cathode-ray bombardment, consists of a very small wrought tungsten "button," 0.1 in. thick, set in a solid block of copper, and this block is electrically welded to a copper stem extending right through the glass anode arm to an external copper radiator. The target with stem and radiator has a heat capacity several times greater than that of the solid tungsten target of the earlier models of the Coolidge tube, and therefore, for a given heavy load, it must take several times as long to heat to redness. What is still more important, unlike the solid tungsten target, it cools rapidly between exposures owing to the radiator, to which is conducted the larger proportion of the energy imparted to the tube. The glass bulb may, therefore, be small, for the glass is not heated to the same extent as in the ordinary tube; each exposure also can be started with a relatively cool target, while, as a further result, the focal spot, although very small, is kept from reaching a temperature high enough to allow inverse current to pass through the tube. The first model of the tube has been designed to carry 10 milliamperes at a 5 in. parallel spark-gap for sufficient time to make the longest ordinary exposures, and, for screening, to carry a load of 5 milliamperes at the same spark-gap indefinitely. A radiograph of the knee is obtainable in four seconds, and exposures for other parts are in proportion. The idea has been to make a tube suitable for portable outfits in the field which can be used directly from the secondary of a high-tension transformer without any auxiliary rectifying device; a portable generating unit, built round this tube, was also exhibited. The advantages claimed for the tube in diagnostic work were that it could be used to rectify its own current under much severer conditions of service than would be permissible with the ordinary type, that the bulb could be very much smaller while handling the same amount of energy, and that on either alternating or rectified current it would carry the maximum available energy for a much longer time. In the portable field x-ray outfit of the United States army, a petrol electric unit supplies alternating current at 110 volts to a transformer arranged to give both high tension and heating currents for the new radiator type of Coolidge tube. For simplicity of control the tube is worked at a constant potential of 5 in. equivalent spark-gap, and the current is adjusted to 5 milliamperes for continuous running of the tube, or to 10 milliamperes for short periods. An electrically actuated control on the throttle of the engine maintains constant output. The small size of the bulb enables a close-fitting lead-glass

shield to be employed; this is made in two parts, and completely surrounds the tube, a suitable aperture permitting egress of the rays.

CANTHARIDES POISONING.

ALTHOUGH the symptoms of cantharides poisoning are generally thought to be well known, the condition of the blood has not attracted any attention. Lipsitz and Cross¹ report a case of a man who accidentally swallowed two drachms of tincture of cantharides, and soon after had strangury and haematuria, followed by vomiting. The haematuria disappeared after two weeks, and the patient was discharged in good condition on the twentieth day. It might naturally be anticipated that this occurrence of severe haematuria would be attended by a secondary anaemia; but on the third day the red blood count was 10,430,000, haemoglobin 80 per cent., and the leucocytes 24,000. On the eleventh day the red cells had fallen to 5,550,000. The possibility that concentration of the blood due to vomiting was the cause of the polycythaemia is not considered, and vomiting was not mentioned after the second day, so it is impossible to be sure if this factor was really important. In conjunction with Fuerth,² the authors investigated the influence of cantharides on twelve rabbits. The drug was introduced into the rabbit's stomach by means of a soft rubber catheter, and polycythaemia appeared within twenty-four to seventy-two hours, and lasted up to eight days; there was also a relative though in no way constant or characteristic leucocytosis. This polycythaemia differs from the transient form following intravenous injection of epinephrin, which has been thought to be due to vaso-constriction of the hepatic vessels and the consequent transference of the red corpuscles to the peripheral circulation. The authors incline to the view that cantharides stimulates the blood-forming organs, possibly by causing haemolysis and a secondary formation of red cells, or brings about a concentration of the blood.

FIRST AID, HOME HYGIENE, AND NURSING IN NATIVE INDIA.

Nor the least valuable outcome of Indian administration has been the awakening and quickening of a sanitary conscience among native communities, commencing with cities and towns and gradually extending to villages and hamlets, spreading from territory under British rule to fensatory native states. Of the latter very satisfactory development the important State of Baroda furnishes a conspicuous example. This territory is fortunate in possessing in the present Gaikwar an enlightened and progressive ruler, and in Mr. Dhanjibhai H. Mehta, L.M. and S., a medical officer whose devotion and energy in the cause of public health are highly commendable. Mr. Mehta has recently published in a pamphlet an address to high school students on the necessity of studying ambulance, nursing, and home hygiene, which he has delivered at various colleges and schools in Western India. In it he emphasizes the duty of correcting conditions and habits which are detrimental to health and adopting measures and precautions conducive to the avoidance of disease and the prolongation of life. He adduces statistics which indicate that sanitary science and practice have in India reduced sickness and mortality among soldiers and prisoners, and contrasts Indian and European death-rates to show how much remains to be done in this direction, and quotes in support of his views extracts from a speech made by the Gaikwar to the Bombay Sanitary Association. Apart from commending public and domestic sanitation, the special object of this address to students and pupils is to impress upon them the advantage of studying first aid and home nursing by joining the St. John Ambulance

¹ S. T. Lipsitz and A. J. Cross: *Arch. Int. Med.*, Chicago, 1917, xx, 1, pp. 389-391.

² S. T. Lipsitz, A. L. Fuerth, and A. J. Cross: *Ibid.*, pp. 915-918.

centres, undergoing instruction, passing examinations, and obtaining certificates and medals. He points out that hygiene and ambulance are compulsory subjects in the university curriculum, and that two important objects may be attained by one course of study. He mentions that "these subjects are taught all over the Baroda Raj since 1901, and 1,500 persons have passed the different examinations." Self-help, both domestic and communal, cannot assume a more commendable, safe, and profitable aspect than that advocated in this address.

SOURCES OF POTASH.

SIR T. E. THORPE, F.R.S., contributed to the last issue of *Nature* an interesting paper on the sources of potash. At one time the world's requirement was obtained from seawater, either directly or indirectly from sea plants (kelp); from wood ashes; from the residue left on distilling fermented beetroot molasses; from the washings of sheep's wool; and from a few other minor sources. In 1839 the Prussian Mining Office ascertained that in a brine area at Stassfurt (near Magdeburg) there were considerable potash formations; they have been worked ever since, but in 1909 large deposits of sylvine, yielding from 10 to 68 per cent. potassium chloride, seldom less than 20 per cent., were discovered in Upper Alsace, near Mulhouse, over an area of about 200 square kilometres. The deposits are in two layers, the lower being the larger and richer. The discovery was made more or less accidentally while boring for coal; the deposits have not yet been fully worked, but in 1912 they were yielding daily 300 tons of sylvine. The product of the factory in which the sylvine is treated is from 40 to 50 tons of pure potassium chloride daily. The amount raised in Alsace was limited by the German Government to about one-tenth of the total German production, the object being to control and strengthen the monopoly Germany had acquired. Spain possesses deposits of potash in Catalonia, but Germany has hitherto been able to prevent their utilization. Italy possesses deposits in Abyssinia, which are now furnishing about 20,000 tons a year; this, however, is only a small fraction of the German output. Stassfurt and other potash beds are derived from primitive rocks, and are due to such minerals as potash feldspar and mica, and certain silicates. Feldspars are estimated to form 48 per cent. of the earth's crust, and their predominant constituent is potash feldspar. Many efforts have been made during the last ten years to devise a process for obtaining potash from the feldspars which contain it. It is stated that large deposits of suitable material are to be met with in this country, notably in Cornwall, and in various parts of Scotland, Wales, and Ireland. A few have been worked for pottery purposes. It is believed that the Scottish deposits could be worked on a commercial scale by a new process described recently by Mr. E. A. Ashcroft, and that potassium chloride, which is the raw material of the potash trade, could be produced at least as favourably in this country as in Germany. Potash salts are needed for munitions of war, for chemical industries, and are essential constituents of manures. Incidentally, if the industry can be established, we may hope to see the price of potash salts, which was artificially high before the war, and has become higher since, substantially reduced.

SYPHILITIC INFECTION OF DOCTORS' HANDS.

DR. H. N. COLE, of Cleveland, Ohio,¹ analyses sixty-one cases of extragenital chancres. In ten the hand was the seat of the primary sore, and in five of these cases the patients were doctors. Infection was traced in the first subject to a small crack between the skin and the external border of the nail on the left thumb. It refused to heal, and at the end of a month the patient felt vague rheumatic pains and dosed himself with aspirin, an eruption which developed a week later being ascribed to that drug; but though it

was discontinued the rash did not disappear, and was seen to be syphilitic. In another instance an open wound at the base of the right index finger became infected during manual removal of the placenta; flooding being severe, the doctor did not put on gloves. The hand was washed with exceptional care directly afterwards, but secondary symptoms developed; then specific treatment was commenced. In the third and fourth cases there was characteristic infection of the right forefinger. In the fifth case the site of the primary lesion was overlooked, but the cubital gland of the right arm became enlarged. The patient had removed the tonsils from a hospital subject under a general anaesthetic a few weeks previously, and noticed immediately afterwards that a syphilitic eruption complicated the tonsillar enlargement. The doctor, not having worn gloves, at once scrubbed his hands vigorously, yet forgot all about the incident until reminded by the appearance of the glandular enlargement. A generalized secondary eruption developed, making the case clear.

MILK IN THE SICK ROOM.

MANY will agree with Dr. George Parker, of Bristol, whose note on the need for a cheap and easily prepared substitute for milk in the dietary of sick adults during the present shortage is printed at p. 53, that the British custom of giving large quantities of milk to almost all invalids without discrimination has little to be said for it except on the score of convenience. The existing scarcity of milk gives a good opportunity for reconsidering the habit of regarding milk as a staple food for the sick. It has grown up in recent times only, but has now become very much a matter of routine especially in hospitals. The malted oatmeal drink suggested by Dr. Parker may or may not prove an ideal substitute, but it will serve at least as a basis for further experiment. The general use of a palatable and easily digested thirst-quenching beverage, easily made at low cost, would release for butter-making large quantities of milk, now consumed in hospitals and sick rooms. Apart from this aspect of the matter, there is the curious delusion common in nurseries and wards that milk quenches thirst. How many thirsty children and fevered patients have been made miserable by cloying draughts of undiluted milk, when all they asked for, or needed, was a drink of cold water! Milk given as a food to infants and young children is, of course, quite another matter.

THE MEAT SHORTAGE.

SOME months ago we pointed out the advantages and disadvantages of a meat diet, and we can by no means be accused of underestimating the value of animal foodstuffs. Nevertheless, we cannot but think that the prominence given in the lay press to existing difficulties in obtaining meat supplies grossly exaggerates their significance, and helps to encourage the enemy and to dishearten our own people. Instead of publishing sensational accounts of butchers' queues, newspapers would do well to mention that the people of this country, like of the inhabitants of many other countries, can adequately supply their need for energy and protein with a very much smaller ration of meat than has been customary in the past. Most people who live sedentary lives will certainly be all the better for the reduction.

THE American Women's Hospitals have sent through the Red Cross some twelve women who will work independently in different places in France. The founders of the American organization were inspired by the example of the Scottish Women's Hospitals. The American women doctors will give civilian as well as military relief both in the United States and in other countries. It is hoped to establish in the devastated parts of the allied countries a system of dispensaries subordinate to central military hospitals. Men not needing hospital care will be attended to at the dispensaries, while serious cases will be taken by ambulance to the nearest general hospital.

THE WAR.

TYPHUS FEVER: LABORATORY DIAGNOSIS.

THE so-called Weil-Felix reaction as a method of diagnosis of typhus fever has been widely accepted by German workers, especially on the Eastern fronts, where, in the Balkans especially, cases of typhus fever have been numerous. The earliest observations on the subject would appear to have been made by Dr. W. James Wilson¹ in Belfast. He published two papers on the subject in the *Journal of Hygiene* in 1909 and 1910 respectively. He showed that in typhus fever the blood serum often agglutinates intestinal bacilli—for example, *B. coli*, *B. typhosus*, and especially a coliform bacillus isolated from the urine in certain cases. In dealing with the etiology of typhus fever he pointed out that the presence of these agglutinins did not necessarily imply that the bacillus in question was of etiological significance, and he inclined to the view that such cases were instances of secondary infection. As the reaction now known in Germany by the name of "Weil-Felix" would appear to be applied there on a large scale it seems well to give some account of the original communication of these authors. So far we have published only brief references to the subject, for hitherto, fortunately, the British armies have been spared this disease. But we cannot be certain that this immunity will continue, and if the louse is indeed the carrier of the infection, one element in its dissemination is not absent. It seems advisable therefore to give some account of their original communication.

Weil and Felix² were investigating a group of cases thought to be enteric fever, but in whom the Widal reaction against typhoid, paratyphoid A, and paratyphoid B was negative even in the uninoculated cases. One of the cases was a Rumanian doctor, who gave completely negative Widal reactions to the enteric group of fevers. From his urine was isolated an organism which was agglutinated by the patient's own serum in a dilution of 1 in 200. It was then found that the serums of nine other patients agglutinated the same organism.

The organism was a short, delicate, Gram-negative bacillus of *proteus* type, and actively motile. On Conrad-Brigalski medium bluish colonies developed, which persisted for weeks. On Endo's medium the colonies were colourless after twenty-four hours, but later became reddish. Glucose and lactose were fermented with production of acid and gas. Milk was coagulated in forty hours. Litmus whey was reddened in twenty-four hours to a greater extent than with *B. typhosus* and to a less extent than with paratyphoid organisms. Gelatin was liquefied in forty-eight hours. The colonies on ordinary plates closely resembled *B. proteus*.

The organism was tested against agglutinating serums for *B. typhosus*, *B. paratyphosus* A, Gaertner's bacillus, Shiga's bacillus, and Flexner's bacillus, and gave negative results with all of them in dilutions of 1 in 100. A serum agglutinating the organism 1 in 2,000 was prepared from a rabbit by injecting 2 c.cm. of an emulsion of the organism on two occasions. In the first place 33 cases diagnosed clinically as typhus were tested against this organism; all of these cases gave a positive agglutination with the organism as follows:

Serums from 16 cases	gave a positive agglutination of 1 in	50.
" "	" "	1 in 100.
" "	" "	1 in 200.
" "	" "	1 in 500.
Serum from 1 case	" "	1 in 25.

Weil and Felix suspected that some of the cases were mixed infections of typhoid and typhus, and in one case typhus fever developed during convalescence from typhoid fever. In 5 of the 33 cases the Widal reaction for typhoid was positive up to 1 in 75, but *B. typhosus* was not recovered. In 5 other cases typhoid bacilli were cultivated from the blood or urine. All the other cases were fully negative to the enteric group.

The specific agglutinin to this organism develops in typhus fever at an early stage of the disease, and has already reached its height when the rash appears (about the fifth day of illness). The high titre remains during the fourteen days or thereabouts of pyrexia, and falls

away quickly after the fever falls. Two months after the end of pyrexia no patient's serum gave a higher agglutination than 1 in 25.

Later Weil and Felix were able to extend their research further afield. In Russia, at a place 200 kilometres from where their first observations were made, two Russian prisoners, not inoculated against typhoid, and giving completely negative Widal reactions to the enteric group of fevers, agglutinated the *proteus*-like organism in dilutions of 1 in 100 and 1 in 200. Three Russian civilians from one family were also examined. One gave a specific agglutination with the organism of 1 in 100 on the second day after the rash appeared. At autopsy in this case the pathological lesions were of typhus fever and not of typhoid. The other two members of the family were already convalescent before they could be examined, but both gave positive results. Eleven cases were also examined in a military typhus hospital in Russia. Only two of these were active cases, the remainder being convalescents. The two active cases (tenth and twelfth days of illness) gave the strongest reactions (1 in 200), two cases were completely negative, and the remaining seven cases all showed gradually decreasing positive reactions depending on the period of convalescence.

As controls, the serums of 169 men were tested, chiefly cases of enteric fever, which is the most difficult disease to distinguish from typhus. Of 95 serums of cases which were clinically typhoid, but in only 11 of which the causative organism was isolated, the test with the *proteus*-like organism was applied. Ten of these cases gave agglutination reactions, but never above 1 in 25. Two cases which were suspected to be typhus fever gave completely negative reactions, and both of these were later shown to be typhoid by the finding of *B. typhosus*. Twelve cases of relapsing fever, in which the causative spirochaete of Obermeyer had been found, gave no agglutination with the bacillus. Sixty-two other men suffering from diseases such as dysentery, enteritis, pneumonia, bronchitis, pleurisy, and erysipelas, gave negative results, but eight gave a reaction in a dilution of 1 in 25.

During the course of the work a similar organism was isolated from the urine of one other case only. The identity of this second strain with the first was fully established by cultural tests and agglutination by the specific serum prepared in a rabbit to the first strain found. During this research organisms were got from the urine of twenty-eight other cases, with cultural characters on Brigalski's medium very similar to the *proteus*-like bacillus, but none of these were agglutinated by the specific rabbit serum or by the serums of positive cases of typhus. This seems to indicate that the organism used for the Weil-Felix reaction is not a common saprophytic infection in man. The authors agree with Wilson that the bacillus is not the cause of typhus fever, but they regard it as an important aid in diagnosis.

This concludes an account of the work done by Weil and Felix in 1915 on which the reaction for the diagnosis of typhus fever has been based. Later, they discovered a second strain of the same bacillus, and to this strain the name *X₁₉* has been applied, the first strain being called *X₂*. The essential difference between the two strains is that *X₁₉* is agglutinated up to a very much higher titre by the serums of typhus cases, up to a dilution of 1 in 2,000, or even higher. Thus the reaction with this strain is much more easy to work with than the much less agglutinable original strain *X₂*. The very agglutinable strain (*X₁₉*) has been found in the urine of cases by a number of later observers (Dienes, Gergely, etc.).

A few of the latest pronouncements in German literature on the value of the Weil-Felix reaction may be mentioned in conclusion. Felix, in a summary of further work, states that his original observations with Weil have been confirmed by numerous observers, to which references are made, in different war areas in Asia and Europe. E. Friedberger⁴ sums up the position of the Weil-Felix reaction as follows. The test is absolutely specific for typhus fever, and an agglutination is not given by any normal serum or the serum in any other febrile disease in a greater dilution than 1 in 100 with the more agglutinable strain (*X₁₉*). In cases of typhus a positive result is given in 90 per cent. of all cases. The agglutination occurs in two hours at 37° C.,

¹ BRITISH MEDICAL JOURNAL, June 16th, 1917, p. 825.

³ *Munch. m-t. Woch.*, September 25th, 1917.

⁴ *Deut. med. Woch.*, No. 42, October 16th, 1917.

and reaches 1 in 1,000 to 2,000, or even higher. The reaction begins very early in the disease, being already 1 in 25 to 50 in the first week. Thereafter the agglutination curve rises rapidly to a pinnacle, and gradually falls during convalescence. Frequently the reaction is quite 1st three or four weeks after all febrile symptoms have passed off. Friedberger considers that the reaction is more marked and specific than the Widal reaction for typhoid fever.

Much discussion has circled round the problem of whether this organism is to be considered in any way as the cause of typhus fever. The general consensus of opinion is that it is not, and this is the belief of Weil and Felix themselves. The most generally accepted opinion is that the organism is a specific secondary invader of the body which always accompanies the unknown virus of typhus fever.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN J. McK. FERGUSON, R.A.M.C.

Captain James McKee Ferguson, R.A.M.C., was reported as killed in action, in the casualty list published on January 3rd. He was educated at Belfast University, where he graduated M.B., B.Ch., and B.A.O. in 1914, took a temporary commission as lieutenant in the R.A.M.C. on December 14th, 1914, and was promoted to captain on completion of a year's service.

Died on Service.

CAPTAIN A. ROBB-SMITH, R.A.M.C.

Captain Alec Robb-Smith, R.A.M.C., was reported as having died on service, in the casualty list published on January 2nd. He was educated at Glasgow University, where he graduated M.B. and C.M. in 1892, and after filling the posts of medical superintendent at Paisley Infirmary and Fever Hospital, at Gockston Small-pox Hospital, and at Croydon Borough Hospital successively, went into practice at Chislehurst, Kent. He joined the R.A.M.C. as a temporary lieutenant in 1916 and was promoted to captain after a year's service.

Captain R. S. Smith, Canadian A.M.C.

Lost at Sea.

Dr. John Edward Lionel Johnston, of the West African Medical Staff, was lost at sea in a ship torpedoed by enemy action, on or about November 9th, 1917. He was the youngest son of Mr. J. C. Johnston, of Bath, and was educated at St. Mary's Hospital, where he gained an open entrance scholarship in 1903. He graduated M.B. and B.S. Lond. in 1909, also taking the M.R.C.S. and L.R.C.P. Lond. in the same year, and the Cambridge diploma in tropical medicine and hygiene in 1912. After acting as junior clinical ophthalmic assistant, as house-physician, and as house-surgeon at St. Mary's, he entered the West African Medical Staff, but had recently been seconded as one of the special investigators under the West African Yellow Fever Commission. He was the author of numerous papers on tropical medicine.

Prisoner of War.

We are informed that news has been received that Captain F. B. Ryan, R.A.M.C., who was reported missing, is a prisoner of war at Heidelberg.

Wounded.

Captain J. H. Barry, D.S.O., R.A.M.C. (temporary).

Captain H. N. Collier, R.A.M.C. (T.F.).

Captain T. M. Crawford, R.A.M.C. (temporary).

Captain H. Dolman, Australian A.M.C.

Captain G. R. Grant, M.C., R.A.M.C. (S.R.).

Captain F. M. S. Hulke, R.A.M.C. (temporary).

Captain J. H. Jordan, R.A.M.C. (T.F.).

Captain F. B. Julian, R.A.M.C. (temporary).

Captain J. F. Matheson, R.A.M.C. (temporary).

Captain A. Ramsbottom, R.A.M.C. (T.F.).

Captain S. H. Seccombe, Australian A.M.C.

Captain L. Zealand, R.A.M.C. (temporary).

Captain and Quartermaster C. J. Fraser, R.A.M.C. (T.F.).

Lieutenant W. H. Newton, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Elliot, Wilfrid E., Second Lieutenant 5th Battalion Dorset Regiment, killed at the taking of Thiepval on September 26th, 1916, aged 24, younger son of Dr. E. A. S. Elliot, Kingsbridge, Devon.

Flanagan, Lionel Christopher, Lieutenant Tank Corps, late Essex Regiment, only son of Dr. Flanagan, of Clacton-on-Sea and of Eyrecourt, co. Galway, killed November 20th, 1917, aged 21. He entered Sandhurst in May, 1915, got his commission in the Essex Regiment in October, 1915, and went to the front soon after. In December, 1916, he transferred to the Tank Corps, and after training went to the front again in July, 1917.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

THE following is a continuation of the list given in our last issue (p. 31) of the New Year awards conferred upon officers of the R.A.M.C., I.M.S., and Dominion medical corps for gallantry and distinguished service in the field:

Bar to the Military Cross.

Temporary Captains: Robert Briffault, M.C., Manrice Smith Bryce, M.C., George Beatty Burwell, M.C., James Macgregor, M.C., Bernard Charles Tennent, M.C.

Military Cross.

Captains (now Majors): John Connor, N.Z.M.C., Wilfred Evans, A.A.M.C., Richard H. Hudson, A.A.M.C., Arthur L. Jones, C.A.M.C., Leonard May, A.A.M.C., Ernest K. Parry, A.A.M.C.

Captain (temporary Major) William W. Greer, M.D., F.R.C.S. Captains: Herbert C. Allison, C.A.M.C., John G. Anderson, William G. Borrie, N.Z.M.C., Charles G. Brentnall, Charles D. M. Buckley, Neil Cantlie, Thomas J. Costello, Thomas McN. Davie, Ian D. Dickson, Keith McK. Doig, A.A.M.C., George S. Elliott, A.A.M.C., Charles P. Fenwick, C.A.M.C., Robert J. Gardiner, C.A.M.C., Kenneth F. Gordon, N.Z.M.C., Frederick J. Green, John C. Grieve, Haji S. G. Haji, I.M.S., Alfred C. Hammond-Searle, Richard T. W. Herald, C.A.M.C., Ernest Hill, S.A.M.C., Leslie E. Hughes, Thomas D. Inch, Frederick N. Johns, N.Z.M.C., Tom R. Kenworthy, William H. Laslett, Reginald H. Leigh, Norman V. Lethian, Henry E. McCready, Thomas McEwen, Kenneth MacLennan, Frank D. Marsh, Henry F. Mandley, A.A.M.C., John Miller, William Murdoch, Charles W. C. Myles, Ivan M. Pirrie, Robert E. Pitts, Leopold T. Poole, Adam Rankine, William L. Robertson, Maurice J. Roche, I.M.S., Cecil J. Rogerson, Edmund U. Russell, Colin C. Simson, A.A.M.C., Evelyn C. Sprawson, Cecil S. Staddon, James Swan, Alan L. S. Tuke, Bernard Varvill, Edmund W. Vaughan, Joseph K. Venables, N.Z.M.C., Joseph Walker, Joseph H. Ward, Robert M. W. Webster, A.A.M.C., William J. Webster, Harry W. Whytock, C.A.M.C., Alexander F. Wilson, William F. Wilson, William V. Wood.

Temporary Captains: Robert R. Archibald, Bertram F. Bartlett, Maurice F. Bliss, Philip R. Boswell, Angus Campbell, George M. Campbell, William T. Collier, Ronald C. Cooke, Alexander K. Cosgrave, John P. Davidson, Henry S. de Boer, Joseph H. Elliott, Herbert Emerson, John C. Fergusson, Lawrence U. Geraty, Edward Gordon, Leonard L. Hadley, John F. C. Haslam, Arthur J. Hawes, Harold G. A. Haynes, Hugh G. Hobson, Gerald Holroyde, John N. Humphrey, Douglas M. Hunter, David L. Hutton, Alick E. Knight, Alexander C. W. Knox, Alec. A. Lees, Kenneth T. Limbery, Percy C. Litchfield, Conrad Loddiges, Reginald H. Lucas, William McConnell, John M. MacFie, William K. McIntyre, Magnus R. Mackay, Eric S. Marshall, James F. Matheson, Archibald U. Millar, Montagu T. Morgan, Reginald S. Morshead, Guy W. Parry, Montgomery P. Paton, George R. B. Purce, Gordon W. R. Rudkin, Walter H. Scott, Leslie H. Skene, Henry J. H. Symons, George L. Thornton, Robert Tindall, Edward C. Wallace, Hugh E. Warwick, Gwilym D. Watkins, D.S.O., John D. Watson, Wm. B. Watson, Llewellyn McI. Weeks, George P. White, Alan Wilson, Charles Witts.

Lieutenant (temporary Captain) John H. Pendred.

Lieutenant William Donald.

Temporary Lieutenants: Ernest H. R. Atounyan, Richard D. Passey.

Quartermasters and honorary Captains: Thomas J. Tilbrook, Herbert E. B. Ware, John F. Murray, A.A.M.C., Richard P. Wheeler, A.A.M.C.

Quartermasters and honorary Lieutenants: James E. H. Anderton, James Davis, Arthur E. Glass, John H. Maunders, James T. Starkie.

The Military Cross has also been conferred upon one non-commissioned officer of the R.A.M.C. and A.A.M.C. respectively.

The D.C.M. is bestowed upon 7 warrant and non-commissioned officers and privates of the R.A.M.C. and 2 of the A.A.M.C. The Meritorious Service Medal is awarded to 53 warrant and non-commissioned officers and privates of the R.A.M.C., 8 of the A.A.M.C., and one each of the C.A.M.C. and N.Z.M.C.

* The announcement of the award of the Military Cross to this officer has not yet appeared in the *London Gazette*, but will be published early this month.

NEW YEAR HONOURS.

ORDER OF THE BRITISH EMPIRE.

IN the New Year's list of promotions in and appointments to the Most Excellent Order of the British Empire appear the following names of members of the medical profession:

To be Knights Commanders.

Colonel Sir George T. Beatson, K.C.B., M.D., Chairman, Scottish Branch, British Red Cross Society.

James Cantlie, M.B., F.R.C.S., Member of Council and of Executive Committee, British Red Cross Society.

Walter Morley Fletcher, M.D., D.Sc., F.R.S., Secretary of the Medical Research Committee.

James Galloway, C.B., M.D., F.R.C.P., Chief Commissioner for Medical Services, Ministry of National Service.

Kenneth W. Goadby, Member of War Office Committee for the Study of Tetanus.

William Henry Thompson, M.D., D.Sc., King's Professor of Physiology, Trinity College, Dublin, Scientific Adviser to the Ministry of Food.

To be Commanders.

Lieut.-Colonel John H. Anderson, Assistant Director of Medical Services, Australian Imperial Force.

Lieut.-Colonel John T. Lewtas, Commissioner for Medical Services, Ministry of National Service.

Colonel Robert Dawson Rudolf, Consultant in Medicine, Canadian Army Medical Corps.

Colonel J. Scott Riddell, M.V.O., Red Cross Commissioner for North-Eastern District of Scotland.

Dr. Lockhart Stephens, County Director, Hampshire, British Red Cross and Order of St. John of Jerusalem.

Dr. T. H. C. Stevenson, Superintendent of Statistics, General Register Office.

Lieut.-Colonel David Wallace, C.M.G., Red Cross Commissioner for Eastern District of Scotland.

Dr. John H. Yolland, Chief of Staff of County Director, Kent, British Red Cross and Order of St. John of Jerusalem.

To be Officers.

Dr. Henry Barnes, LL.D., J.P., Honorary Secretary and Treasurer, Cumberland Branch, British Red Cross Society; a past President of the British Medical Association.

Major Lionel O. Betts, A.A.M.C.

Dr. Herbert E. Cuff, Principal Medical Officer to the Metropolitan Asylums Board.

Dr. Thomas C. Dillon, H.M. Consul, Porto Alegre, Brazil.

Dr. Richard H. Grimby, Assistant County Director, Ashburton Division, British Red Cross and Order of St. John of Jerusalem; Deputy Commissioner of St. John, Devonshire.

Major Hugh B. Lewers, Assistant Director of Medical Services, Australian Imperial Forces.

Arthur F. MacCallan, F.R.C.S., Director of Ophthalmic Hospitals, Egypt.

Dr. Finlay M. Mackenzie, J.P.

Captain Edmund Distin Maddick, F.R.C.S.

Major Thomas McKibbin, Deputy Assistant Director of Medical Services, New Zealand Expeditionary Force.

Dr. Sarat K. Mullick, Honorary Secretary, Bengalee Regiment Committee.

Dr. George Reid, M.O.H. Staffordshire County Council.

Dr. John Robertson, M.O.H. Birmingham.

Dr. John Russell, Vice-President of Burslem and Tunstall Division, and Assistant County Director for the North Staffordshire Area, British Red Cross and Order of St. John of Jerusalem.

Dr. Charles Stein, Commandant and Medical Officer, Park House Auxiliary Hospital, Shipston-on-Stour, Warwickshire.

Lieut.-Colonel Edward N. Thornton, South African Hospital, Richmond Park.

Brevet Colonel G. Sims Woodhead, V.D., R.A.M.C., Professor of Pathology, Cambridge.

Joseph Ainsworth Woods, Senior Dental Surgeon, Mürren, Switzerland.

Lieutenant-Commander Eric Worsley Gandy, R.N.V.R.

To be Members.

Lieut.-Colonel Harry H. Balfour, South African Hospital, Richmond Park.

Lieut.-Colonel William J. Bentley, Assistant Director of Dental Services, Canadian Forces.

Dr. Francis R. Cassidy, Officer-in-Charge, Transport of First Line Hospitals, Derbyshire.

Dr. Arthur V. Davies, Assistant County Director, representing the Order of St. John of Jerusalem, East Lancashire.

Captain Percy T. Remington, Dental Officer, Australian Army Medical Corps.

Herbert L. Rutter, F.R.C.S., Officer in Charge of Wounded Convoys, Northumberland.

Major Thomas L. L. Sandes, South African Hospital, Richmond Park.

Captain Arthur F. Sutton, Senior Dental Officer, Australian Army Medical Corps.

Major Walter H. Tofft, Australian Army Medical Corps.

Mrs. Ella G. A. Webb, M.D., Lady District Superintendent, St. John Ambulance Brigade, Dublin.

RED CROSS WORK.

Work for the Red Cross is recognized by the dignity of Dames of the Grand Cross conferred upon Lady Amphill, Mrs.

Benyon, Lady Dawson, the Duchess of Montrose, and Viscountess Northcliffe, and Dames Commanders on Mrs. Godman (Horsham), Lady Jekyll, Mrs. Locke-King Surrey, Mrs. Ker Pryse-Rice (Carmarthen), and Mrs. Webster (British Women's Hospitals). Mr. Kenderdine's work for the Hospital for the Limbless, Rochampton, is recognized by K.B.E., and Sir John Furley's Red Cross work by his appointment to be Companion of honour.

Scotland.

THE EDENHALL HOSTEL FOR LIMBLESS SAILORS AND SOLDIERS.

THE Edenhall Hostel for Limbless Sailors and Soldiers, established near Kelso in June, 1915, and therefore second in date only to Rochampton, is about to be removed to Musselburgh. A house standing on a site of thirteen acres has been acquired, and the change will have two main advantages: first, that it will be possible to increase the accommodation to one hundred beds and the facilities for making artificial limbs; and, secondly, that the new situation, being near Edinburgh, will be in many respects more convenient. The hospital was founded by the Countess of Home, the commandant is Lady Isobel Douglas Home, the matron in charge Mrs. George Henderson, and Dr. Henderson of Coldstream, a member of the committee of management, has voluntarily given his services. Lieut.-Colonel Cathcart, R.A.M.C., has superintended the fitting of the artificial limbs, and will now become a member of the committee. The establishment of the home for limbless sailors and soldiers at Erskine House, near Glasgow, has made it desirable to allocate different areas to the two institutions. The Edenhall Hostel will in future serve for limbless men domiciled in the east of Scotland, while Erskine House will receive those from the west. In order to provide accommodation for one hundred men on the new site considerable extensions are necessary, and these are already in hand. The cost of the alterations, extension, and equipment is estimated at £12,000, and the whole of this sum will be provided by the Scottish Branch of the British Red Cross Society, but an appeal is made for contributions to meet the general expenses, for extra comforts for the men, and for additional equipment. The financial secretaries and treasurers are Messrs. William Home, Cook, and Co., C.A., 42, Castle Street, Edinburgh.

THE UNIVERSITY OF EDINBURGH IN 1916-17.

The annual report for the academic year 1916-17 shows that the matriculated students number 1,201 men and 686 women; of the male students, 152 matriculated for the purpose of joining the Officers' Training Corps, in addition to those who in the ordinary course were in attendance at classes. In the faculty of medicine there were 709 men and 240 women. Of the students of medicine, 465, or nearly 50 per cent., belonged to Scotland, 144, or over 15 per cent., to England and Wales, 30 to Ireland, and 281, or 29½ per cent., to British Dominions, including 76 from India. There were also 29 from foreign countries. The number of graduates, officials, and students, past and present, serving in H.M. Forces is now considerably over 5,000, and more than 400 have died. Many of the departments in the faculties of science and medicine have been occupied with work which has a direct bearing upon the war. It is noted that the funds transferred to the University Court by the Royal Victoria Hospital Tuberculosis Trust for the foundation of the Chair of Tuberculosis amounted to £18,000.

EDINBURGH ROYAL INFIRMARY.

During the year ending October 1st, 1917, the number of in-patients admitted to the Royal Infirmary, Edinburgh, was 11,181, of whom 847 (7.04 per cent.) died. Of the patients admitted 5,039 lived in Edinburgh and Leith, and 6,142 in other parts of Scotland. Three large wards with 116 beds have been held constantly at the disposal of the military authorities for the treatment of men from the expeditionary forces, and during the year 36 sailors and 663 soldiers were treated therein. The managers have entered into agreements with the Edinburgh and East Lothian War Pensions Committee for the treatment of discharged sailors and soldiers other than those suffering from diseases for which special hospitals are provided.

England and Wales.

THE INCORPORATED SOCIETY OF TRAINED MASSEUSES.

At the second annual general meeting of the Institute of Massage and Remedial Gymnastics, held at Manchester on December 7th, 1917, with Sir William Cobbett, president, in the chair, Sir William Milligan, chairman of the executive council, made an important statement with regard to the future of the institute. Since July, 1916, negotiations have been in progress between representatives of the institute and of the Incorporated Society of Trained Masseuses, which now has a membership of over 4,000. The points of difference in the constitution of the two bodies were discussed, and notes were made of changes which the institute considered essential in the working policy of the society before any common ground of action could be reached. As the outcome of a conference a scheme for the reconstitution of the society was approved by both councils. This includes provision for the admission of male certificate holders to membership and representation, a change of title to show that the society is not confined to masseuses, and the setting up of local boards in order to decentralize the growing general work of the society. Sir William Milligan, on behalf of the council, urged members of the institute to accept amalgamation, by which both bodies hoped to secure what was essential in the interests of massage generally—namely, a uniform training, and a "one portal" examination system. This course was unanimously agreed to by the meeting. The suggested reconstitution and amalgamation, if carried into effect, should enlarge the scope and strengthen the position of the Incorporated Society. We learn from the *Journal of the Incorporated Society of Trained Masseuses* that the proposals will be laid before the members thereof at special general meetings to be called early this year.

MATERNITY AND CHILD WELFARE.

There are at present five voluntary infant welfare centres in operation in the Metropolitan Borough of Wandsworth, and a sixth will commence work this month. Steps have been taken to link up the work of each of these voluntary centres with the work of the council in connexion with home visiting, and in January, 1917, the council decided to contribute to the funds of the five centres then in operation to the extent of 25 per cent. of their annual expenditure on condition that the total contribution of the council did not exceed £250 in any one year (that is, 25 per cent. of a gross annual expenditure of £1,000 in the borough). In March, 1917, the council decided to enter into arrangements with the various nursing associations in the borough for their nurses to attend cases of measles when requested by the medical officer of health, and payment is made to the associations at the rate of eightpence a visit. In May, 1917, this work was extended to include cases of ophthalmia neonatorum. In July, 1917, the council resolved to enter into an arrangement to pay for the services of medical practitioners when called in by registered certified midwives in cases of emergency amongst necessitous women, and the following is the scale of fees paid for such services:

1. For all cases necessitating operative assistance or exhibiting special difficulties, and subsequent visits for next ten days ...	£	s.	d.
2. For attendances in cases without operative assistance and subsequent visits for next ten days ...	1	1	0
3. For attendance for administration of an anæsthetic ...	1	1	0

Canada.

THE HALIFAX EXPLOSION.

The number of deaths in the Halifax tragedy is now given officially as 1,226. It is probable, of course, that other deaths will occur as the result of exposure; the explosion and consequent fire were followed by an icy blizzard with terrific wind, heavy snowfall, and rain, culminating in zero weather, all of which made it often impossible to continue the work of rescue. Almost every pane of glass in Halifax

was smashed by the explosion, and numbers of people sustained injury through the bits of glass that were sent flying in all directions. It is stated that from two to five hundred persons have been partially or totally blinded. Among the buildings destroyed were the Rockhead Military Hospital, situated on the pier, and the infectious diseases hospital, from both of which, however, the patients escaped; also the Home for the Deaf, and the Protestant Orphanage, where a number of children were killed. The loss of property, of course, is very great, and it is estimated that from twenty-five to thirty million dollars at least will be required to provide for the homeless and to rehabilitate the destroyed area. The presence in the city at the time of the explosion of a number of military units facilitated the maintenance of order, and command of the relief work was taken by Lieut.-Colonel McKelvie Bell, C.A.M.C. It was fortunate also that the Camp Hill Hospital had just been completed, and could be used to accommodate some of the wounded. Upon receipt of the news of the explosion a number of doctors went at once to the scene of the disaster. A medical unit sent from Boston, Massachusetts, was of the greatest service.

ESTABLISHMENT OF MILITARY HOSPITALS.

A number of military hospitals are in process of construction by the Military Hospitals Commission. One is now being built on a site adjacent to the Macdonald College at Ste. Anne de Bellevue, about twenty miles from Montreal. Macdonald College comprises a School of Agriculture, a School of Domestic Science, and the Protestant School for Teachers of the Province of Quebec, so that it offers excellent facilities for vocational education. The new hospital will be beautifully situated on the banks of the Ottawa River, near its junction with the St. Lawrence. Plans have also been prepared for a hospital of 1,000 beds at High Park, Toronto, on the plan of the Ontario Hospital at Orpington. Other hospitals are being built at Kingston and London, Ontario, and one was recently opened at Moose Jaw, Saskatchewan.

In connexion with the work of the Military Orthopaedic Hospital at Toronto, which is the centre of this work in Canada, research is being conducted at Hart House, Toronto, into devices for the treatment of cases of functional loss or impairment, and arrangements are being made for standardized equipment, which will be installed in each of the military convalescent hospitals. Each case is treated individually and, when necessary, a special appliance is adapted or made to suit the requirements of that particular case. A device is attached to each appliance to register the progress made by the patient from day to day, an arrangement which has been found to be of great benefit to the patient, as it encourages him to make every effort to improve. A survey of all the convalescent hospitals established by the Military Hospitals Commission was recently made by Major Tait McKenzie for purposes of co-ordination and standardization of methods.

Correspondence.

A WHOLE-TIME SALARIED MEDICAL SERVICE.

SIR,—There is one point of view, difficult to express, which many must see more or less clearly, which seems to me the most essential problem to be considered when a whole-time medical service is under discussion, and that is the ability or inability of the medical man to give a correct and definite opinion to any given patient.

It is one thing to be a free man taking no further responsibility towards one's patients than saying, "That is my best advice and you can follow it or else consult someone else," and it is another thing to say, "That is my advice and I expect you to be guided by it." When we consider seriously the mistakes we have made, and those we have observed made by better men than ourselves, are we really prepared to say that medical science is sufficiently exact in practice to be put into a general State system?

It is normal for the newly qualified to feel pretty confident; it is more or less natural that the public health service should make rather light of the responsibility of taking over such things as the treatment of tuberculosis; and no doubt private practitioners and members of

voluntary hospital staffs manage to keep a full share of confidence in themselves, but they certainly learn, year by year, that the practice of medicine is a very responsible calling; and I believe those most capable of giving a sound opinion are those least inclined to shoulder the responsibility of being placed in a position in which the advice might be given to a patient who did not seek it, or at any rate had no choice of the doctor who should give it; and further, more important still, the situation might be very difficult if the patient declined to follow out the advice. But to repeat my main contention, is there any member of the profession capable of giving definite advice on individual cases, which advice the State is justified in expecting the patient to adopt? If a man chooses his panel doctor, if he chooses his private practitioner, if he chooses his hospital, or his hospital consultant, he has come more than half way towards taking his (the patient's) share of the responsibility; but can he choose a salaried officer? Or could he choose to choose no officer at all?

The position of a medical referee is often very doubtful; the society may be asking questions which no medical man can answer; and it is we ourselves who have the necessary expert knowledge to know our limitations, and it is our duty to have the courage to state them.

There are many attractions about a whole-time salaried post under the State; many men holding temporary commissions are hoping for such a service when we demobilize, but except in special departments I wish to suggest that ordinary civil practice will not easily be carried out under a system comparable to that of the army. It is right for a man to hold views on certain points so strongly that he will decline to treat people who will not carry out his directions. But is he justified in forcing his views on patients who may not individually have chosen him?—I am, etc.,

December 31st, 1917.

TEMPORARY COMMISSION.

THE MINISTRY OF NATIONAL SERVICE.

SIR,—The letter of "X" does not seem to have evoked the interest in medical circles which one would have expected. Let us hope that the letter of "Y" will be more successful. Presumably appreciation of the magnitude of the issues involved in the setting up of the Ministry of National Service has not yet percolated through a profession the members of which have many absorbing duties.

With the idealism of "X" I am not concerned, nor with the pessimism of "Y" with regard to the political wisdom of the British Medical Association. But "Y" at all events has recognized the potentialities of the new Ministry after the war. Will the Ministry continue to make use of voluntary assistance from the statutory professional committees, or will the force of circumstances compel the absorption of these bodies into the machinery of a Government department?

The information obtainable by the statutory committees is essential to the Ministry. This information is being gathered for the medical profession by the medical profession at the cost of its own bodies. It is conceivable that presently difference of opinion may arise between the Ministry and the committees with regard to the nature, form of record, or use of the information acquired. Discussions on such differences of opinion will not lead to efficiency.

In my opinion the time has arrived when the whole of the work of the statutory professional committees should be transferred to the Ministry of National Service. Where possible, use should be made of the Local Medical War Committees in connexion with the department. But in cases where any difficulty arises in maintaining connexion between the Ministry of National Service and the local profession in each area as represented by the local committees, the Ministry can avail itself of the machinery of which it already has a nucleus in the shape of its deputy commissioners.

The transference to a Government department of a piece of work which has been due purely to voluntary effort is probably a difficult matter. But for the sake of ultimate efficiency it should be undertaken forthwith.—I am, etc.,

January 6th.

THE TREATMENT OF TRAUMATIC PARAPLEGIA.

SIR,—In answer to Colonel Percy Sargent's criticisms on my article on this subject may I say that I am sorry if I did not make my meaning clear—that it is only for cases clearly incurable that I raised the question of an attempt being made to establish conductivity between the upper and lower segments of the divided spinal cord?

Quite a number of cases of spinal injury are now being operated on at the front, a short time after the wound has been inflicted, when it is readily ascertainable whether there is complete division of the cord, and therefore if the patient is likely to remain paraplegic, should he recover from the primary injury and the accompanying bladder trouble.

In later cases, if complete paraplegia has existed for some months after injury without any signs of returning functions, this would, I consider, prove that the cord had been divided or permanently injured, and that the paraplegia would persist with its attendant distressing symptoms and dangers associated with paralysis of the bladder and rectum. In only such hopeless cases do I advocate an attempt being made to bring about relief by trying to establish continuity of the conducting tracks.

The ideal operation would be to bring together the divided ends of the spinal cord; but this could only be done by shortening the spine, as the cord cannot be stretched to make the ends meet.

Waller taught many years ago that the axis cylinder is a branch of a nerve cell which grows towards the periphery, and Howell and Huber, twenty-five years ago, arrived at the conclusion that although the peripheral structures are active in preparing the scaffolding, the axis cylinder is the essential portion of a nerve fibre, which has an exclusively central origin.

I am quite aware that the peripheral nerves differ from the medullated fibres of the spinal cord in not possessing a neurilemma sheath, and that Purves Stewart, Ballance, and Bethe advanced the view that new nerve fibres have a peripheral origin; but other eminent observers, such as Langley, Anderson, and S. Ramon y Cajal have defended the older Wallerian doctrine.

It is on the Wallerian view that it would seem to me possible that the axis cylinders may project processes through a small sector of living cord introduced between the two ends of the divided cord.

About the success of my case of transplanted spinal cord into the gap in a median nerve of a man there can be no question, for the case was followed up for years, was a complete success in every respect, and was seen by many medical men. I explained his case on the Wallerian theory, rightly or wrongly.

The man subsequently earned his living for some years as a platelayer on the North-Eastern Railway, and was ultimately killed on the line while on duty; unfortunately I did not hear of his death for a week, and then it was too late to try to obtain permission to examine the nerve that had been operated on.—I am, etc.,

London, S.W., Jan. 8th.

A. W. MAYO-ROBSON.

FLIES IN WINTER.

SIR,—The following observation appears to be contrary to the views of Captain McDonnell.¹

I have a small ancient week-end cottage in the country. During October, November, and the first two and a half weeks of December, 1917, it was shut up. Severe frosts had occurred during this time, and the cottage is a cold one. We paid a short visit on December 19th; fires had been lighted the day before. About 8 p.m. my wife went up to the children's room, and on moving the curtains over an old deep-set window found black masses of semi-torpid flies clustered closely together. I crushed a large number, probably several hundred, but left one black mass of nearly a hundred flies untouched, and a number of disturbed flies crawling about, as I thought it would be cleaner and more complete to kill them with formalin next morning. I got the formalin at mid-day, but on moving the covering curtains found all the flies had gone, and their new resting place could not be found. These flies had therefore withstood severe frost and two and a half months

¹ BRITISH MEDICAL JOURNAL, January 5th, p. 25.

in a house to which no food had been brought, and were still capable of moving off when disturbed, so it is rational to suppose that they could have existed throughout the winter.—I am, etc.,

A. WINKELRIED WILLIAMS, M.B., C.M., D.P.H.

Brighton, Jan. 8th.

MENTAL EXERTION AND THE PROTEIN RATION.

SIR.—It won't do. It will not do at all to trust that the protein will take care of itself if only we give or take sufficient calories. The cases I have published show that a man may consume enough calories to keep him in physical health and ample weight, and yet his mental health may suffer from lack of protein. And the experiments of Atwater and Benedict won't do either. They found, you say, that the intensity of metabolism is not affected by mental work. This denies what I did not assert. I do not say that the intensity of the general metabolism is affected by mental work; but if, as we most of us think, the amount of mental activity is a measure of the activity of the brain, the metabolism of the brain must *a priori* be increased during mental activity. All that Atwater and Benedict's experiments show is that they did not find evidence of increased metabolism of the brain. But if, as I contend, the working metabolism of the brain is mainly a protein metabolism, were they likely to find an increase in it? Protein is not, as the carbohydrates are, stored in the body until wanted, and its products excreted in proportion to the activity of the body. Any excess of protein intake beyond what is needed for the service of the body is reduced to urea and excreted at once, along with the urea reduced from the protein that has been utilized. The amount of CO_2 that is excreted is a measure of the sugar that has been used. The amount of urea that is excreted is a measure of the protein that has been absorbed; and what proportion of the absorbed protein has been used we have no means of knowing. It is customary to assume that the activity of the brain may be measured by the amount of phosphates excreted, but this is a pure assumption, and rests on no evidence that I know of. It was made in Germany.

It would seem that the only way to determine whether the protein excretion is increased by brain activity would be to stop the intake of protein and compare the excretion of urea during a period of mental activity with the excretion during a period of mental rest; but the stoppage of the protein intake would so disturb the conditions that the result would not be trustworthy.

We are here reduced to speculation, and must speculate as best we can on the basic fact that a certain minimum amount of protein over and above the amount necessary to preserve the physical health, is necessary to the minimum of normal mental exertion. This is proved by my published cases. I submit that it is reasonable and safe to suppose that more mental exertion means the using up of more protein, and that better mental work will be done on a liberal ration of protein than on a bare minimum. I do not wish to convey the notion that a dullard can be converted into a genius by stuffing him with meat, but I have a strong opinion, based on my own experience, that the dullard will be less dull on a liberal protein ration than on a scanty one. I think it probable, also, that the genius will be nearer the top of his form in the same circumstances, but as to this I have no personal experience.

Finally, Sir, let me repudiate the aspersion that I have any quarrel either with you, or with the Food Controller, or with any one. My record is surely sufficient evidence of a nature almost morbidly averse to quarrelling.—I am, etc.,

Parkstone, Dorset, Jan. 7th.

CHAS. MERCIER.

* * Dr. Mercier says he has no quarrel with us, and we have certainly no quarrel with him. We did not quote the experiments of Atwater and his colleagues as evidence that the metabolism of the brain was not increased by mental activity but as evidence that the magnitude of any change, whether in terms of energy or of protein, was not such as need be brought into account when the question is one of rationing. Dr. Mercier may be quite right in thinking that more protein is needed by a man engaged in mental work than by the same man physically fit

although mentally inactive; but the interval between the minimum amount of protein necessary for physical health (less than 40 grams according to Rubner and Thomas) and the amount provided by a war diet which also yields the *needed energy*, is so great that we still hold, *pace* Dr. Mercier, that calories *will* do, if we can get them; but with the material now before them readers will be able to form their own judgement.

THE SANATORIUM TREATMENT OF TUBERCULOSIS.

SIR.—Your leading article of December 8th, 1917, clearly emphasizes the failure of sanatorium treatment for tuberculosis as a whole, and one cannot emphasize too strongly that the treatment of such cases very much resolves itself into one of environment.

Many of the sanatoriums have done good work in arresting the disease, and it is equally true that too many of the sanatoriums are little better than boarding houses—thus the treatment is not what it should be. It is comparatively easy to forecast a cure or arrest of the disease in the hæmorrhagic type, but in the catarrhal forms the outlook is very different, and to obtain amelioration of the symptoms a differentiation has to be made and a distinct line of treatment enforced; this, I believe, is not systematically carried out in many of the so-called sanatoriums, so, from a public point of view, failures arise.

The treatment and experience of Brechmer and Walther are frequently traded upon, and too little adopted in their true and practical aspects. Brechmer not only selected a proper site for his sanatorium, but he lived the life of his patients; he not only understood his cases, but enforced his treatment; even then disappointments occurred, and plainly due to "environment"—namely, the return to old associations and a lesser resistance.

Possibly the effect of exposure to strong "rainy winds," as Dr. Gordon says, has its influence, and no doubt he writes with knowledge of the conditions in his own district. I write with some experience, and I agree with him in saying sanatoriums are valuable when properly situated and skilfully handled; for this purpose there must be a dry subsoil, moderate rainfall, no dust or fog, but sunshine and protection from wind.—I am, etc.,

Bournemouth, Dec. 13th, 1917.

A. KINSEY-MORGAN.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR.—May I call attention again to the injustice which is being done to some of those medical students who, in 1914, sacrificed their future to the need of their country? I refer to those students who, in their first and second year, responded *at once* to the urgent call (how urgent seems to have been forgotten) of those dark days. A cynical Government now says, "Fools! why did you not wait until you had passed your second professional examination? Because you were over-hasty, you must give way to those who, with much greater sense, looked before they leaped. Besides, if you had been more careful you need not have come at all." Others, more loftily, say, "Be content! look at the great satisfaction your noble patriotism will bring to you in after-life." Which, of course, is quite true. Pure patriotism is, without doubt, an excellent thing, and carries with it a noble and pure reward, even if it lands you in the workhouse. It would appear, however, that the reward is much more tangible if your patriotism is seasoned with a little self-interest.

My son, who was within six months of passing his second professional when he joined the army in 1914, is now told that, had he been a little less hasty in the exercise of his patriotic instincts, he would now have been free to return to his medical studies. As it is, he has suffered the horrors of Gallipoli and Mesopotamia, only to find that his claims are disregarded in favour of those who chose to "wait and see," and now find themselves rewarded by the gift of both the substance and the shadow by a grateful country. Is the army in such need of men that this injustice to these brave men is to continue? Surely not!—I am, etc.,

January 6th.

J. A. A.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

The second appeal for subscriptions to this fund was published in the *BRITISH MEDICAL JOURNAL* on December 29th. The fund is now so low that unless liberal support is shortly obtained it will be necessary very largely to diminish if not altogether to suspend the monthly contributions which were kept up regularly throughout last year. The following subscriptions have been received up to the end of last week:

£ s. d.		£ s. d.	
Dr. Herbert Spencer	25 0 0	Dr. S. M. Salaman	1 0 0
Mr. J. B. Lawford	5 0 0	Dr. C. D. Muspratt	5 0 0
Mr. W. C. Bull	10 10 0	Dr. E. W. Collinson	5 5 0
Dr. Middleton	5 5 0	Dr. H. Russell Andrews	5 5 0
Dr. George Hunter	1 1 0	Dr. F. E. Batten	5 0 0
Dr. A. E. Nicholls	2 2 0	Dr. F. J. Baildon	1 1 0
Dr. Lawrence Franklin	10 10 0	Dr. D. R. Moir	1 1 0
Mr. J. Elliot Square	5 0 0	Mr. T. Jenner Verrall	2 2 0
Dr. J. B. Hurry	1 1 0	Miss Price	1 0 0
Mr. F. Neal	0 10 0	Mr. Frederic Durham	2 2 0
Dr. J. W. Carr	5 0 0	Dr. R. Hingson Fox	1 1 0
Dr. Alfred Cox	2 2 0	Dr. D. Fogarty	1 1 0
Sir St. Clair Thompson	10 10 0	Dr. W. B. Russell	0 7 6
Dr. John Matthews	10 10 0	Professor T. K. Monro	5 5 0
"Anonymous"	5 0 0	Per Sir Rickman J. Godlee	3 10 0

The treasurer also desires to acknowledge the receipt of £8 14s. 10d. from the Pharmacy Board of New Zealand, received through Mr. C. W. Nielson, the Registrar.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

The Serbians.

DEPUTY DIRECTOR-GENERAL A.M.S.

COLONEL T. H. J. C. GOODWIN, C.M.G., D.S.O., who has been representing the British Army Medical Service in America, has been appointed Deputy Director-General, Army Medical Service, on the retirement of Surgeon-General Sir M. W. Russell, K.C.M.G., C.B. Colonel Goodwin's place in America will, we understand, be taken by Colonel C. K. Morgan, C.M.G., who has been serving on Sir Arthur Sloggett's staff in France.

AUXILIARY R.A.M.C. FUNDS.

At the conclusion of the first complete year of the existence of the Auxiliary R.A.M.C. Funds it is thought that all officers of the Auxiliary Forces will be interested to hear something of the measure of success which has been attained in promoting the objects for which the funds were established.

Initiated by the Director-General, Surgeon-General Sir Alfred Keogh, G.C.B., in June, 1916, the idea soon began to take shape, and a committee was formed in August which undertook the management of the funds subject to the approval of the annual general meeting.

Circulars were sent out to all officers, and subscriptions invited first from officers of the auxiliary forces for the benevolent branch for the assistance of orphans of deceased officers who may have left their families in difficult circumstances, with a view to obtaining for the children a better education than would have otherwise been possible; and secondly from canteen and recreation funds for the relief branch for the immediate needs of widows and orphans of soldiers of the corps of the new armies who have lost their lives during the war. All moneys received have been kept separately in the two branches, the accounts being kept quite distinct.

As regards the benevolent branch, it was decided that in all cases assistance should be made by grants annually, such grants being renewable as circumstances required, but being always reviewed by each general annual meeting. The committee has been authorized to deal with urgent cases as they arise during the year by making small grants in advance subject to the approval of the next annual meeting, and also with the administration of the relief branch.

The first annual general meeting was held on October 26th, and grants made from the benevolent branch as follows:

3 orphans of an officer with temporary commission	430
2 " " " " " "	520
2 " " " " " "	540
2 " " " " " "	215
4 " " " " " "	431
2 " " " " " "	125
R.A.M.C. Territorial Forces	

Cases which have been reported since the meeting have been dealt with by the committee under the powers delegated to them, and no doubt others will arise as the existence and objects of the funds become better known.

Sir Alfred Keogh has continued to take a great interest in the fund, and in September last addressed a personal letter to all Directors of Medical Services at home and abroad inviting their co-operation. As a result the number of annual subscribers has greatly increased, and the total at present exceeds

1,200, and a considerable amount of money has been invested in War Loan and National War Bonds to make provision for future calls. The success and future development of the charity may, therefore, now be considered to be assured, provided that the corresponding annual subscriptions are continued, which there is no reason to doubt.

In the earlier days there seems to have been some misunderstanding as to the objects of the funds, and some officers appeared to think that they were in some way undertaking duties which should be met from public sources. Grants from these funds in no way take the place of any pension, compassionate allowance, or gratuities to which the families of deceased officers or warrant or non-commissioned officers or men may be entitled under the Royal Warrant for Pay, etc. The funds are a charity pure and simple, and registered under the War Charities Act, 1916, and grants are made solely in aid of orphans and widows and orphans in the relief branch, and are allotted according to the circumstances of each individual case after taking into consideration the total income of the applicants, including any pension, etc., of which they may be in receipt.

Colonel W. Hale White, R.A.M.C.T., has kindly undertaken the duties of Honorary Secretary, and the office will shortly be moved to 11, Chandos Street, Cavendish Square, S.W.1. After January 31st all communications should be sent to that address.

EXCHANGE.

MEDICAL OFFICER in charge (H.D.) Squadron R.F.C., Norfolk, wishes exchange with Medical Officer in charge barge in Flanders. Address No. 200, BRITISH MEDICAL JOURNAL Office, 423, Strand, W.C.

Obituary.

DR. EDWARD SERGEANT, consulting M.O.H. Lancashire, sends a personal appreciation of the late Dr. Thomas Fisher, whose death was announced in the *JOURNAL* of December 29th:

For a period of five years (Dr. Sergeant writes) Dr. Fisher was a fellow student of mine at St. Thomas's Hospital, and during the time I held the position of house-surgeon he was one of my best dressers. He held the position of M.O.H. to the Garstang Rural District Council for thirty-five years, and as county medical officer of health I frequently visited his district and can speak in the highest terms of his worth and the valuable assistance I received from him on matters relating to public health. Special mention may be made of his help in the formation of a large small-pox hospital area for the districts comprised within the Fylde, Preston, and Garstang Unions. He also rendered great assistance in matters relating to the occurrence of tuberculosis and in respect of a local outbreak of poliomyelitis, more recently also in anthrax. Notwithstanding the heavy pressure of the work of his profession, Dr. Fisher took the greatest interest in agriculture and was personally a large landowner and practical farmer. Dr. Fisher's unexpected death came as a great shock and deep grief to a very wide circle of friends in this county, many of whom, for a prolonged period, had been accustomed to regard him as a dear friend and trusted medical adviser.

WE regret to record the death of Dr. JOHN POLSON which took place towards the end of last August at Newland, Cape Peninsula. The son of Dr. James Polson, he was born in April, 1837, in Aberdeenshire, and graduated M.D. at Aberdeen University in 1859. For sixteen years he practised in a Forfarshire village, but on account of his wife's health he left for South Africa in 1879. He was a most popular and successful practitioner in Reddersburg, having a large practice among the Dutch farmers. At the time of the Boer war he retired from work and after visiting the old country he made his home in the Colony. Whether in Scotland or in the Free State his geniality and fine character made him beloved and respected by all who knew him.

MAJOR P. D. SICCARDI, of the Clinique of Industrial Diseases in Milan, died in hospital in Pavia on December 22nd, 1917, as the result of a small abrasion of the skin which became infected while injecting spirochaete virus. He had made ietero-haemorrhagic spirochaetosis among the Italian troops his special study, and had carried out many researches. When Porto Rico was annexed by the United States of America, Siccardi was at the time waging a successful campaign against ankylostomiasis in that country. He was a frequent contributor to the subject of occupational diseases and to the solution of public health problems. A hard worker and a careful observer, his death is a great loss not only to Italy but to social and preventive medicine generally. In the Milan clinic Major Siccardi was for a considerable period closely associated with Professor Devoto, to whom he acted as assistant.

Medical News.

THE Minister of Pensions has appointed Sir John Collie, C.M.G., to be Director of Medical Services for the Ministry of Pensions.

PROFESSOR TUFFIER, of Paris, has been promoted to the rank of Commander of the Legion of Honour in recognition of his eminent services as consulting surgeon to the French armies.

At the meeting of the Royal Microscopical Society at 8 p.m. on Wednesday next, Mr. E. Heron-Allen will deliver his presidential address on the society during the great war and after.

A MEETING of the Tuberculosis Society will be held on Monday, January 21st, at 8 p.m., at the Royal Society of Medicine, 1, Wimpole Street, W., when a discussion on farm colonies in the treatment of tuberculosis will be opened by Sir Robert Philip, Dr. T. Dyke Acland, Dr. Noel Bardswell, and Dr. A. H. Macpherson.

As Padua has recently been the objective of Austrian air raiders, the rectorate and Academic Council of the famous university have been by official decree transferred temporarily to Pisa. The same decree authorized the Minister of Education to allow professors of Padua to lecture in other universities and superior institutions.

A COURSE of public lectures on some biological problems of to-day will be given at University College, London, during January, February, and March. The first lecture, on the problem of food, will be given by Professor W. M. Bayliss, F.R.S., on Monday, January 21st; the second, on war bread and its constituents, by Professor F. G. Hopkins, F.R.S., on January 28th; the third, on accessory food factors (vitamines) in war diets, by Miss E. Margaret Hume, of the Lister Institute, on February 4th; and the fourth, on alcoholic and other beverages, by Professor Cushny, on February 11th. All the lectures will be given at 4 p.m., and are open free to the public.

At the last session of the General Medical Council a report was received from the Public Health Committee recommending certain modifications in the resolutions and rules regarding diplomas in public health, with a view to recognition of laboratory experience by medical officers serving with a British Expeditionary Force. The recommendation, which was printed in the SUPPLEMENT of December 8th, 1917, p. 113, was adopted by the Council. This has necessitated a revision of the existing resolutions and rules, and we are asked to state that a new edition has accordingly been prepared containing the additional provisions which will hold good for the duration of the war.

DR. FILOMENA CORVINI, who has been working as a medical officer, with the rank of lieutenant, at the Italian front, recently returned to Chieti, her native town, where she had an enthusiastic welcome. She was afterwards received in private audience by the Queen of Italy, who expressed keen interest in her work. Other Italian women doctors are taking their share in war work. Dr. Elena Fambri, of Venice, has attended the wounded in the advanced line, while Dr. Serena De Paoli, who remained at her post in the Children's Department of the Civil Hospital at Venice, suddenly found herself in the zone of military operations and at once took up the duties created by the new situation.

THE lecture arrangements of the Royal College of Surgeons of England for February are as follows: On February 6th, on the surgical treatment of neuragia, by Mr. Jonathan Hutchinson; on February 8th, on the treatment of war injuries of the jaw and face, by Mr. Percival P. Cole; on February 11th, on the diagnosis and treatment of syphilis of the central nervous system, by Dr. Hildred Carlill; on February 13th and 15th, on the *Quaderni d'Anatomia* by Leonardo da Vinci, by Professor William Wright; on February 18th, on the structure of the English skull, by Mr. F. G. Parsons; on February 20th and 22nd, on projectile fracture of limb bones, by Mr. E. K. Martin; and on February 25th, on the pathological aspect of certain war injuries of the eye, by Colonel W. T. Lister, C.M.G. Professor Keith will resume on January 14th his course of lectures on the anatomical and physiological principles underlying the treatment of injuries to muscles, joints, and bones. All the lectures are given at 5 p.m.

AN artificial limb manual training centre at the Boulevard, Balham, was opened by Mr. Samuel Samuel, M.P., on January 8th. It has been established as a piece of war philanthropy by the local traders' association. It is to receive and instruct men who have been newly fitted with artificial limbs at Rochester and elsewhere. The men, under the guidance of competent instructors, are first to

be put through some elementary training in the use of their new limbs: afterwards they are to be passed on to more delicate and complicated movements, and ultimately, it is hoped, to the use of tools appertaining to various trades before being drafted to technical centres for expert instruction in special handicrafts. The centre consists of three large rooms fitted with benches and with various appliances for exercising arm and leg movements. It was stated that many men, after discharge from convalescent homes, grow discouraged by their inability to use their artificial limbs to full advantage, and sometimes even discard them. Daily classes of free instruction will, it is hoped, quickly make them proficient.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

ANSWERS.

"PERPLEXED," who desires to hear of a home for an epileptic man, aged 36, is recommended to communicate with the secretary (Mr. Penn Gaskell), National Association for Epileptics (Chalfont Colony), Denison House, Vauxhall Bridge Road, S.W.1.

LETTERS, NOTES, ETC.

CIVIL SURGEONS IN MILITARY HOSPITALS.

COLONIAL writes: "C. S." in his letter in the JOURNAL of January 5th, p. 40, calls attention to a very important matter, and one which is worthy of the attention of the Association. In the Boer war civil surgeons on military service were allowed to wear a distinctive uniform. In the present war no such privilege has been accorded to them, nor the right of wearing any distinguishing badge showing that they are doing war work. Civil surgeons engaged as whole-time medical officers in military hospitals, doing orderly duty, etc., ought to be granted permission to wear uniform with a distinctive badge. They do not ask for commissioned rank, but it is right that as medical officers in military hospitals they should wear uniform to show their position, and take their proper standing with their colleagues who hold commissioned rank.

THE WHITE BREAD CURE.

THE habitual use of white bread is comparatively a novelty even in France. Avenel, than whom there is no better authority on such matters, quotes an entry from a householder's account book in 1765, showing that he advanced to a maid in his employment 1.65 francs for "a purge and some white bread." As the servant's wages for the year were probably less than 80 francs, this was a considerable sum to her. White bread, Avenel explains, was then looked upon as a remedy.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

				£ s. d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE MEDICAL ASPECTS OF AEROPLANE ACCIDENTS.*

BY

H. GRAEME ANDERSON, M.B., CH.B., F.R.C.S.,
TEMPORARY SURGEON R.N., ATTACHED ROYAL NAVAL
AIR SERVICE;

SENIOR ASSISTANT SURGEON, ST. MARK'S HOSPITAL, LONDON,
AND TO THE BELGRAVE HOSPITAL, LONDON.

In the early days of flying there were necessarily many accidents, owing first to structural weaknesses in the aeroplanes and secondly to the fact that the pioneer pilots had to experiment and were mostly unacquainted with many of the factors governing aerial navigation. When man began to teach man, and as improvements in the construction of aeroplanes increased, so accidents diminished in number proportionately; but, on the other hand, many more took up flying, and the total of accidents was increased. The pre-war methods of teaching were slow and sure, and first solo flights were made in stages, and after prolonged tuition, thus tending almost to obviate accidents altogether. As the war advanced and the importance of aviation was recognized more pilots were needed and the methods of teaching had to be accelerated; after a few hours' dual-control instruction, pupils were sent off to do their first solo flights. Naturally many more accidents occurred, and as nowadays tuition is on faster and more powerful aeroplanes, so have the total number of accidents increased. Every accident teaches something new, and all should be investigated thoroughly, so that a preventable cause or error can be eliminated in the future. In this connexion the reports of the Public Safety and Accidents Investigation Committee of the Royal Aero Club are very instructive and should be studied.

The total number of accidents due to school work and experimental flying is greatly augmented by the number due to war flying, either the result of aerial duels or anti-aircraft fire from the ground.

An attempt has been made to classify accidents at this station covering a period of six months, and these are referred to as the "V" series. In a general review of accidents I have also drawn from fifteen months' experience whilst at another school, and these are referred to as the "E" series.

In the "V" series during six months 4,000 hours' flying were done, consisting of 9,000 flights, and during that time 58 aeroplanes were wrecked or crashed. The suggested definition of a crash is an aeroplane so damaged in a flying accident that it has to be deleted or sent into the workshops for repair or rebuilding. This is in contradistinction to the effects of a bad landing or get off where the ensuing damage is small and can be repaired by the flight mechanics. Fifty-eight crashes in 9,000 flights represents one crash in every 155 flights. In these 58 crashes 16 airmen were injured, which is equivalent to 28 injuries in every 100 crashes, or one pupil injured in every 560 flights.

From these figures one can see that school flying is fairly safe and compares favourably with other high velocity forms of transit.

From this list of 58 crashes the following table is compiled to show the frequency of crashes and injuries on early solo flights:

No. of Solo.	No. of Crashes.			No. of Solo.	No. of Crashes.		
	With Injury to Pilot.	Without Injury to Pilot.	Total.		With Injury to Pilot.	Without Injury to Pilot.	Total.
1st	1	8	9	8th	0	1	1
2nd	5	4	9	9th	0	2	2
3rd	1	3	4	10th	0	1	1
4th	0	3	3	12th	1	1	2
5th	1	2	3	After 10 hrs.	2	12	14
6th	0	1	1	Dual control	1	0	1
7th	3	5	8				
Total		15	43	58

* Abstract of an article published in the *Journal of the Royal Naval Medical Service*, January, 1918.

The table shows a greater frequency of crashes on the first and second solos, then a diminution from the third to the sixth inclusive, and a rapid rise again on the seventh. The inference suggested is that by the time the pupil arrives at his seventh solo he becomes over-confident and a little careless.

CAUSES OF AEROPLANE ACCIDENTS.

The causes of aeroplane accidents are: (1) defect in the aeroplane; (2) error in judgement in flying; (3) "loss of head"; (4) brain fatigue or lethargy; (5) fear; (6) physical illness; (7) unavoidable causes.

In an analysis of the 58 crashes in the V series the following table shows the frequency of these causes:

Cause.	Number of Crashes.		
	With Injury to Pilot.	Without Injury to Pilot.	Total.
1. Aeroplane defect: (a) Breakage (b) Engine failure	1 —	0 —	1 —
2. Error of judgement	4	38	42
3. Loss of head	6	1	7
4. Brain fatigue	3	1	4
5. Fear	0	0	0
6. Physical illness	0	0	0
7. Unavoidable	1	3	4
Total	15	43	58

I. Defect in Aeroplane.

This implies mechanical failure of some part of the aeroplane, and can be subdivided into (a) breakage in the air, and (b) engine failure.

(a) *Breakage*.—In the early days of aviation breakage or giving way in the air of some vital part of the aeroplane—for example, the folding back of a wing—was fairly common, and was due to faulty design or weakness in construction. Happily, to a great extent this has been corrected, and at the present time very few accidents are due to this cause. In three years' experience with the R.N.A.S. I have not seen a machine actually break in the air. In one case in the E series an elevator control wire jammed and caused the aeroplane to nose-dive, with fatal results to both occupants.

(b) *Engine Failure*.—Engine failure *per se* may be a direct cause of an aeroplane accident—for example, if the engine fails just as the aeroplane is leaving the ground, and there is unsuitable landing ground, the pilot may not have sufficient height or air space to avoid obstacles in front. Or in landing the pilot may find in his glide downwards that he has undershot or overshot the mark and his engine will not "pick up" or respond to carry him on further to suitable landing ground.

On the other hand, engine failure may not be a direct cause but may be a strong contributory or indirect cause of an accident. In all cases if the engine fails in the air a forced landing is compulsory, but given a fair height—2,000 ft. or more—the pilot can usually select a good field for landing and arrange his descent accordingly. Of course, on approaching the field to land it may be found not quite so good as imagined from a greater height—for example, sloping ground, long grass, etc.—and thus the pilot may make an error of judgement on actually landing. This quite often occurs with a pupil, but rarely with an experienced aviator, who knows exactly how to "pancake" his machine. But even in the case of experienced aviators, engine failure just after leaving the ground is a strong contributory cause to the real cause of an accident—namely, an error of judgement in flying. Authorities cite as one of the commonest examples of aeroplane accidents engine failure just after leaving the ground, when the pilot tries to turn back to his original starting-place loses height in the turning, and, in trying to prolong his glide, loses flying speed—stalls—and the aeroplane falls to the ground out of control. In the V series engine failure was the direct cause in one case, and was a contributory cause in two cases.

2. Error of Judgement.

Error of judgement in flying is the commonest cause of aeroplane accidents. This error may occur in getting off the ground, in the air, or on landing.

Of the 58 crashes in the V series this cause accounted for 42—4 in getting off the ground, and 38 on landing. Of the many examples of error of judgement in flying perhaps the commonest is when, on landing, the pupil misjudges his distance from the ground, and either "flattens out" too soon and "pancakes," with a possible crash depending on the height, or else "flattens out" too late, and strikes the ground at a varying angle, usually overturning and wrecking the machine. Other examples in the air are putting on too much "bank" with insufficient "rudder" or vice versa; climbing on a turn; and, as in engine failure, prolonging a "glide" so that the machine loses flying speed.

It is difficult to estimate and account for these errors of judgement. In some cases it may be due to under-instruction. In other cases, even after prolonged instruction, the pupil may still misjudge distances, and on examination one occasionally finds that his standard of vision is below normal; but, on the other hand, he may be found physically fit, with normal vision and good balancing power. In the latter cases it may be a question of delayed reaction time, especially the visual reaction time on which the aviator is so much dependent. Normally this reaction time takes $\frac{1}{10}$ or $\frac{2}{10}$ of a second. It may be delayed by fatigue, drugs, and excesses, but, on the other hand, in some individuals who are otherwise physically fit, it is found to be much slower than in others. Hence, in the selection of candidates for aviation the visual and other reaction times must be up to the normal standard. By the French medical authorities on aviation candidates are rejected if the reaction times are found to be of the delayed type.

3. Loss of Head.

Loss of head occurs fairly frequently in a greater or less degree, and accounts for a fair proportion of accidents—7 in the present V series. The pupil in his new occupation of flying for the first time has all his mental faculties on the alert, at extreme high tension; the sense of danger, although not asserting itself, is ever-present, but subconscious. Under the sudden strain of an emergency his power to reason and act synchronously may momentarily lapse, resulting in what is known as loss of head. In a critical position the pupil has to think, decide, and act quickly, but with loss of head the mental balance becomes upset: there is no mental inertia, but the wrong decision is taken and acted on. In flying, seconds and parts of a second count enormously, and may mean all the difference between safety and danger. After actual loss of head there is seldom time to correct the error made. As examples of loss of head in the air the pupil in an emergency may move the throttle the wrong way, may keep his engine full on when he should throttle down, or may switch off his engine at a moment when he requires all the flying speed possible. Loss of head is very much allied to the two following causes.

4. Brain Fatigue.

In contradistinction to loss of head, the pupil in brain fatigue reaches the stage where he has neither the power to reason, decide, or act. A state of mental inertia supervenes. This is due to repeated stimuli received by his brain in rapid succession in his flight—he feels alone; a succession of errors occur in the air; he feels he cannot manage to control the aeroplane; fear does not seize him, but the enormity of the whole thing appals him; he feels helpless, and a state of brain fatigue occurs in which he, in a stupor, awaits events and takes little part in the aeroplane's control. After a careful study of 100 of the first solo flight confessions of pupils, and of many pupils who have had crashes, I am convinced that brain fatigue is a cause of a fair proportion of accidents. Four occurred in the 58 of the V series. As a rule, in brain fatigue the pupil fails to flatten out, and the aeroplane strikes the ground at its gliding angle and becomes wrecked. On questioning a suspected case of brain fatigue immediately after his flight, one finds usually that there is very little recollection of what happened during the flight; memory seems to become partially stunned. It is difficult to make a diagnosis of those liable to brain fatigue. As a rule, if it occurs, the pupil, even should he escape injury, soon gives up flying. He is not of the temperament suitable for flying. As a preventive, the pupil's first few solo flights should always be of short duration.

5. Fear.

Fear, at least in a degree sufficient to disturb one's flying, is rarely experienced in the air on the first few solo flights, whatever the sensations may be before going up or in the intervals between flying. The mind is far too much occupied and concentrated on details of flying, watching the various instruments that record air speed, height, levels, and engine's revolutions, and in judging position and direction in the air relative to the ground. From an analysis of the confessions of the first solo flights of 100 pupils and of my own, it is curious to note that very few experience fear in the air, at least not in a degree sufficient to disturb flying. Many confess to a sense of danger lurking somewhere at the back of the head, but say that it rarely if ever asserts itself. In the V series no crash occurred through fear.

6. Physical Illness.

In the series of crashes under consideration none was attributable to physical illness. At an air station medical inspection of the pilots and pupils at regular intervals reveals any organic disease that might lead to loss of consciousness in the air.

Flying on an empty stomach may cause faintness in the air. In schools flying commences at dawn, and all pupils are provided with a good meal of cocoa, tea, bread-and-butter. Similarly on long flights pilots are provided with tabloid forms of nourishment. The effects of cold and fatigue may produce faintness or stupor in the air. There are many instances on record of pilots fainting in the air either through being wounded or from high altitude effects. Some have been known to recover consciousness before reaching the ground and to make successful landings. Two pupils in the E series suffered from attacks of malaria in the air, and both were made to discontinue flying. Another pupil in E series, although slow to learn, was making fair progress, but one day he was noticed to descend rather steeply; he made no attempt to flatten out, the aeroplane struck the ground at its gliding angle, and the pilot was thrown out, clear of the machine, a distance of 66 ft., and escaped with only a slight sprain of one ankle. A few days later in the wardroom this pupil was seized with a series of typical epileptic fits. On inquiry a history of epilepsy for the previous five years was elicited. This was undoubtedly a case of an epileptic fit taking place in the air.

7. Unavoidable Causes.

From time to time unavoidable accidents arise. Every precaution is taken at a flying school to prevent collisions in the air or on the ground. Set signals are made with regard to the direction of circuits and landing areas for different flights. The terrain in certain areas may be unsuitable and conceal obstacles; again, in some aeroplanes the view of the sky or ground in certain positions may be limited. These conditions may cause unavoidable accidents. In the V series four accidents were unavoidable. Two were due to bad terrain with obstacles concealed in the grass; in the case of the other two a collision took place in the air.

TYPE OF ACCIDENTS.

The term "type of accident" has been suggested to describe the part of the flight in which the cause of the accident was initiated. It is possible to make an arbitrary division of a flight into three parts: First, the getting off the ground into the air up to 50 or 100 feet; second, in the air, with the various turns, figures of eight, climb, spirals, etc.; and, third, the landing, which includes the descent from the time the throttle is closed to the time the aeroplane is brought to a standstill on the ground.

The following table gives an analysis of the types in the V series:

Type of Accident.	No. of Crashes.		
	With Injury to Pilot.	Without Injury to Pilot.	Total.
1. In getting off	4	6	10
2. In the air	2	0	2
3. In landing	9	37	46
Total	15	43	58

Some of the errors which the pupil may make in getting off are raising the aeroplane's tail too high, slewing to one side, or getting off with one wing down. In the air a pupil may lose flying speed or stall, or may sideslip or spin. The commonest

type of accident is in landing—the pupil's *bête noire*. He may either flatten out too soon, lose flying speed some feet from the ground, and the machine "pancake," or else he may be too late in attempting to flatten out, and the aeroplane strikes the ground at an angle, turns over, and is wrecked.

SCHEME FOR FIRST AID AT AN AIR STATION.

The sick-bay or dressing station should be in full view of the aerodrome, with a look-out man supplied with field glasses always on duty during flying hours. Should the dressing station not be situated on the aerodrome, the former should be connected by telephone to the look-out man, whose position commands a good view of the flying area. Immediately a crash or false landing occurs, the look-out man telephones to the sick-bay notifying the steward the exact site of its occurrence. A map of the aerodrome, numbered in quadrants, can be conveniently arranged in the sick-bay. The look-out man then leaves his post and proceeds to the scene of accident, taking the wheeled hand stretcher, on which is carried a first aid dressing bag and an emergency tool kit case. The latter consists of an oblong box containing the following:

1. Two crowbars.
2. Two strong wire cutters.
3. Saw.
4. A long stout knife.
5. A hammer.
6. Strong cloth cutting scissors.
7. A fire extinguisher.

The above set of implements is very necessary, as in some crashes where the pilot is pinned under the wreckage it may be difficult to reach him. An injured aviator should never be dragged out of a crash unless in the case of fire, but rather the wrecked machine should be cut away from him. In many cases this prevents simple fractures from being converted into compound ones. The steward on being notified of an accident dispatches the ambulance, which stands always in readiness by the sick-bay, to the scene of the accident. The ambulance should be provided with twin wheels aft in order to facilitate movements on soft earth, etc. Two sick berth attendants go with the ambulance, and with them is a bag containing the following articles:

1. Morphine solution and two Willey's hypodermic syringes.
2. A bottle of chloroform and face mask.
3. Brandy.
4. A bottle of sterilized water.
5. Six first-aid field dressings and slings.
6. Picric acid dressings.
7. A tourniquet, cloth cutting scissors, and a knife.

These articles can easily be packed into a small bag 10 in. by 8 in. by 3 in. The surgeon on duty is on the aerodrome during flying hours, and proceeds to the scene of the accident by car or foot. If the accident is at a distance, a mile or more, it is better to go by aeroplane. I have now gone by air to over thirty forced landings and accidents at a distance, and am convinced of the utility of this method in arriving quickly and not otherwise tired and out of breath after a long run. In discovering the site of forced landings and accidents at a distance from the aerodrome much depends on the condition of the country around. Should this be flat country, these accidents are fairly easily discovered, but in some flying schools the surrounding land may be uneven, intersected with dykes and high-hedged roads. Thus it may be extremely difficult for the search party to find the wreck. Officers and flight mechanics sent to the scene of accident should be trained in first aid with special reference to aeroplane accidents. Flying pupils should not be allowed to come near or help, except in exceptional circumstances.

Often the crash is so severe that the wreckage has to be cut away from the injured aviator. In other cases the machine is upside down, with the pilot held head downwards by his safety belt. The latter must be cut and the pilot slid gently out. The emergency tools are used to cut wires, remove wreckage, and lever away the heavy parts—for example, the engine—and thus easily to reach the injured person. The aeroplane seat cushion is taken from the machine and placed under the injured pilot's head, while his body rests on a flying coat spread out on the ground. A rapid examination is carried out to determine the injuries received. If the injured person is conscious and in much pain morphine should be injected and he should be conveyed quickly to the dressing station, where clothes can be cut away, injuries examined, and

treated accordingly. If unconscious, some cutting away of clothing can be done on the field, injuries examined, and perhaps a dislocation reduced or a fracture accurately diagnosed during the unconscious period. In cases of fire, unless the pilot is thrown clear, the extinguishers must be used; but if there is any wind blowing they are of little use, as an aeroplane on fire is destroyed completely within a few minutes. The pilot's leather clothing for a time usually protects the body, but the face and lower limbs rarely escape. As the pain is so severe, and this applies to other injuries apart from those caused by fire, it is better to give chloroform on the field, and this is kept up on the way back to the dressing station. Morphine should also be given, but it takes some time to act.

SOME FACTORS RELATIVE TO AEROPLANE ACCIDENTS.

The injuries sustained are akin to most high velocity accidents, but are usually more severe as greater speed is used in aviation. They are composed of—

1. Injuries due to crushing, where some part of the pilot's body gets crushed between parts of the wrecked aeroplane. Crushing injuries are very severe in nature and mostly fatal in the propeller type of aeroplane (engine behind).
2. Injuries due to collision with the ground, as when the pilot is thrown out, or hits the ground with his head in turning over in and with the aeroplane.
3. Injuries due to impact with different parts of the aeroplane, as when the head is violently jerked forward and strikes the edge of the nacelle on the aeroplane's impact with the ground. Flying debris, such as broken struts and wires, may cause local impact injuries.
4. Injuries from fire.
5. Drowning and immersion effects in seaplane work.
6. Suspension effects, as when the pilot is suspended head downwards in an overturned aeroplane and is unable to loosen his safety belt. In many crashes the sudden impact of the pilot's body on the safety belt causes abdominal injury.

The injuries sustained vary a good deal, and depend on the type and power of the aeroplane and the cause and type of accident. An experience of three years attached to the Royal Naval Air Service impresses me more and more with the element of luck which befalls pilots in crashes. The present-day school aeroplane is much stronger in construction and more powerfully engined than in earlier days, thus providing for a greater margin of error on the pupil's part. The propeller type of school machine (for example, the Maurice-Farman) is considered very safe. It can be landed slowly, and has a powerful engine to cover errors. In a crash it has a strong undercarriage and a great deal of woodwork to absorb the shock before actual injury occurs to the pilot. On the other hand, in a nose dive in this type of machine the engine, being behind, is likely to crush the pilot severely, and this usually proves fatal. In tractor machines the engine in front takes most of the shock in a crash, but the observer's seat just behind the engine usually gets telescoped or crumpled sideways. The pilot's seat, which is behind these, usually escapes crushing effects. If the pilot receives injury, this occurs either from his being thrown out or from his head being violently jerked forward and hitting the nacelle edge, windscreen, or instrument board. Should the safety belt hold, the sudden impact of the pilot's abdomen and lower part of chest against it may cause internal injuries. Nowadays most nacelle edges are padded, and safety belts are stronger and braier.

Safety Belts.—With regard to the use of safety belts, endless discussion has taken place amongst aviators. My own opinion is that before leaving the ground all aviators should see that their safety belts are fastened and should be familiar with the method of their quick release. The belt should never be undone in the air. Thus the pilot, in the event of fainting, losing consciousness, or being wounded, or encountering gusty and bumpy weather or fog, has a safeguard to prevent him either being thrown out in the air or thrown forward on to his control lever (thus causing the aeroplane to nose-dive), or having his feet jerked off the rudder bar (thus losing steering power). I think all are agreed on the above, but the difficult question arises whether to release the belt near the end of a glide before landing. This I would advise in the propeller type of aeroplane, but in the tractor machines it remains an open question.

Certainly if the aeroplane catches fire in a crash little hope can be entertained of the pilot if he be strapped in. Safety for him depends on his being thrown out clear of the machine. A narrow belt is to be condemned. The

ideal safety belt should be broad and resilient, attached to the framework of the aeroplane and not to the pilot's seat, should be made to release easily and quickly, not at the centre of the pilot's body but at the side where it is attached to the aeroplane. This release should be effected by means of a small hand lever. It is advisable for all pilots to carry a stout knife in the outside pocket of their flying coat in order to cut the belt should they be held in upside down after a crash.

Safety Helmets.—These are of undoubted value in school work and should be worn by all pupils. They should fit properly and not be easily dislodged whilst flying. The modern ones are much lighter and less high in the crown than the earlier ones used. In a crash they certainly prevent scalp wounds from broken struts and wires and the side flaps protect the ears from injury. Over and over again I have seen pilots thrown out who owe their escape from more or less serious head wounds to their safety helmets.

On the other hand, in a turn over, the added height of the crown may catch the ground and wrench the head either forwards or backwards, causing fracture dislocation of the neck, or severe strain and possible rupture of the muscles of neck and back.

As pointed out by Fleet Surgeon Wells, an ideal safety helmet would take its support from the shoulders.

Goggles.—Most aviators wear goggles, but there are still some who prefer to fly without them. I know of one instructor who, after a year continuously instructing pupils and wearing no goggles, began to suffer from a form of conjunctivitis. I certainly think that goggles should always be worn. There is no doubt that flying without goggles is apt to set up a spasm in the eyes which in the long run is bound to do harm. Triplex or non-splintering material is now almost universally used instead of glass in the manufacture of aviation goggles. Thus rarely in a crash do we get any injury to the eyes. The nose-piece connecting the two lunettes should have no metal in its composition. I have seen some cases where wounds of the nose were caused by the metal connecting part of the lunettes.

Accidents under Dual Control.—Accidents under dual control are not common, as the instructor has usually time to correct in the air any of the pupil's errors in flying. One occurred in the V series, and was unavoidable owing to the character of the ground. In the E series three occurred. All dual control machines should be fitted with a mechanical device for throwing out of action quickly the pupil's control of the machine. I have seen three other crashes under dual control but without injury to either instructor or pupil.

Fatal Accidents.—In two years of school work I have only seen three fatal accidents occur in roughly 200 crashes. Four deaths occurred, of which three were instantaneous and one after four days. All were due to multiple injuries.

ACUTE YELLOW ATROPHY IN SYPHILIS.

(A Preliminary Note.)

By STUART McDONALD, M.D., F.R.C.P. EDIN.,

PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

DURING the past two months I have had the opportunity of studying in the *post-mortem* room no fewer than five typical cases of acute yellow atrophy, an experience which must be almost if not quite unique. Though numerous examples of subacute types of the disease have been recorded in recent years, and particularly in munition workers, typical cases of the classical icterus gravis are seen only at long intervals. According to Best¹ (1903) only some 500 cases of acute yellow atrophy were on record at that time.

In a personal experience of over 5,000 *post-mortem* examinations performed since 1898 I have only investigated one other case. The present series of five cases have all occurred in syphilitic subjects in the course of, or subsequent to, treatment by "salvarsan" preparations and mercury; and considering the number of cases of syphilis now being treated throughout the country, a searching

analysis of these fatal cases would appear to be urgently called for to determine, if possible, the relative parts played as etiological factors by the syphilitic toxin, arsenic, and possibly some other exciting agent.

I do not propose in this communication to describe the details of the observed cases, these being reserved for a later and fuller joint report, but would content myself at present with a brief summary of the essential facts.

In practically all the cases a full course of intravenous injections of salvarsan had been given, coupled with the usual intramuscular injections of mercury. Needless to say, in each case the diagnosis of syphilis was not only clear on clinical grounds, but was confirmed by a Wassermann test. These cases were not of undue severity, and indeed showed no special symptom of importance till a sudden onset of jaundice was noticed, without at first any special disturbance, the disease suggesting nothing more than an ordinary catarrhal jaundice.

At a varying period of from two to eight days, however, acute symptoms appeared with dramatic suddenness. They were ushered in by a period of wild excitement and increased icterus, with haematemesis. The patients rapidly passed into a condition of deep coma, and death occurred in the five cases at periods of one to four days from the onset of the acute symptoms.

The urine was markedly bile stained, and in each case showed tyrosin; in some leucin was also demonstrated. In four of the cases diminution in the size of the liver was demonstrated during life.

These cases, then, presented clinically the classical symptoms and signs of icterus gravis of a degree of acuteness which is seldom seen. The morbid anatomy and histology of these cases were equally striking and equally characteristic, the appearances being practically identical, and varying only in degree. To summarize the *post-mortem* results, there was in each case great diminution in the size of the liver, which varied in weight from 27 to 43 oz. Histologically there was the usual intense necrosis rather than a fatty degeneration of the liver parenchyma, the bile duct epithelium largely escaping; there had been, of course, no time for liver-cell regeneration, but a definite inflammatory reaction was present. Though "red" areas were macroscopically apparent in the liver, the condition has been so acute that in most cases the "yellow" areas preponderated. It is to be noted, however, that the naked-eye appearances give no adequate indication of the extensive changes found microscopically. In each case there has been widespread haemorrhages in the serous membranes with a special haemorrhagic infiltration of the lungs. The kidneys, in contrast with the liver, have shown an intense degree of fatty change, with, in some instances, definite signs of an inflammatory reaction. There has been constantly noted also a varying degree of intestinal catarrh.

Bacteriological examination has, in contrast to what has been hitherto found in similar cases, yielded some interesting results which may prove of prime importance in relation to the etiology of the condition. Cultures from the heart blood and lung have given copious growths of organisms apparently of the *coli*-typhoid group, with some definite cultural characteristic features and pathogenic properties (in two at least out of the three strains tested so far). I am unable to say more at present, as their cultural and biological reactions are still being investigated, and as the bacteriology of acute yellow atrophy has hitherto been so indefinite, one must be chary of attaching too much importance to their presence without some experimental evidence of an etiological relationship with the disease. One may be permitted, however, to review briefly the present opinions as to the causation of acute yellow atrophy, or rather acute necrosis as it should be called, and to note how the various hypotheses which have been advanced would apply to the present group of cases. In 1908² I endeavoured to summarize the current views at that time from a study of an acute case, and a series of subacute cases which I had personally observed, and particularly from a series of cases which had been observed in that year in Germany and America.

To quote from that paper, I stated

that there is much to be said in favour of the view that in the causation of acute yellow atrophy we have two factors at least at work. It may well be that the typical condition is

only produced when some special virus acts on a previously damaged liver;

and again,

that the most reasonable view to take would appear to be that the essential cause of acute yellow atrophy is some poison, possibly of microbic nature, produced in the alimentary tract and acting on a liver previously damaged, or whose function at least has been disturbed.

I do not, of course, claim originality for this view; it has been held by others, no doubt, both before and since. I only present it again as a working hypothesis.

The damage to the liver may be produced, as we know, by metabolic poisons—for example, in eclampsia and allied conditions—and there is now abundant evidence that syphilis may in the same way be an essential factor in paving the way for the development of acute yellow atrophy in another group of cases. That syphilis produces definite changes in the liver is common knowledge. The existence of gummata and cirrhosis in both congenital and acquired syphilis is common, but it is apparently not so widely recognized, except by those who are treating large numbers of cases of syphilis, that jaundice is not so very uncommon. According to various authorities, it would appear to occur in from 1 to 2 per cent. in cases treated in the German clinics.

It has also been long recognized that syphilis is not an uncommon precursor of typical acute yellow atrophy, and was noted long before salvarsan was ever used as a curative agent. In 1898 Richter collected 41 cases, and, though later Veszpremi and Kanitz,⁸ in a criticism of Richter's observations, cast doubt on the presence of syphilis in ten of these cases, numerous observations on acute yellow atrophy since leave no doubt that syphilis has been present in a very large number of instances. In another group of cases, poisons not of microbic nature have fallen under suspicion; thus phosphorus, arsenic, mercury, chloroform, and, in quite recent years, trinitrotoluene and tetrachlorethane, have been shown capable of producing changes in the liver which are comparable at least to those seen in icterus gravis. An analysis, however, of most of these cases reveals certain differences from the *post-mortem* findings in typical acute yellow atrophy either in the histological or chemical results of investigation of the liver or in the rapidity with which the condition develops. Thus, in the case of phosphorus and delayed chloroform poisoning, though the symptoms may closely simulate those of acute atrophy, there is a degree of "visible" fatty change which is not apparently seen in the classical acute atrophy, as was pointed out by Sir H. J. Stiles and myself⁴ in a paper on delayed chloroform poisoning in 1904. Tiletson⁵ has recorded a case of acute atrophy, apparently resulting from mercury, where syphilis was not present. I have only found one definite reference to arsenic as a causal agent.

Severin⁶ in 1912 described cases of acute atrophy in syphilitic cases under treatment by salvarsan, though Wells⁷ (1914) refers generally to such cases, and doubtless an examination of recent literature, to which I have not access at present, would reveal other examples.

Fresh interest in the subject has been stimulated since the outbreak of war by the study of toxic jaundice in munition workers, in whom a large number of cases of jaundice have been observed. In 1916, 181 cases occurred in T.N.T. factories in this country alone, with 52 deaths. The subject was discussed at the Royal Society of Medicine in January, 1917,⁸ and the Medical Research Committee has recently issued a monograph on the subject, which I have not yet seen.*

The trinitrotoluene, according to the investigations of Dr. B. Moore, appears to be largely, if not entirely, introduced into the body through the skin, and the *post-mortem* results reveal a condition, as M. Stewart states, somewhere between subacute atrophy of the liver and portal cirrhosis. One case, however, which he describes, though not in detail, in his contribution to the discussion at the Royal Society of Medicine, would appear in its clinical course and morbid anatomy to be indistinguishable from a typical case of acute yellow atrophy.

It may be remarked that these cases occurred particularly in munition workers who had shown definite symptoms of toxic gastritis, and it is possible that even in

them the gastro-intestinal catarrh is in some way associated with a secondary intestinal infection, acting on a previously damaged liver. *Post-mortem* examinations in these, for the most part subacute cases, might not reveal the microbic invasion which has been so marked in the present series. Still less likely would *post-mortem* examination throw much light on the etiology of the by no means inconsiderable number of cases of subacute atrophy which occur for the most part in children without any previous history of "poisoning" or infection.

These cases have not till comparatively recently been widely recognized, in this country at least. In 1908, together with Dr. Lindsay S. Milne,⁹ I published a series of five such cases in which the clinical histories and *post-mortem* appearances left no doubt as to their true nature, but owing to the longer clinical course run, little light could be thrown on the primary cause of the condition.

In still another group of cases, namely, undoubted septicaemia from various organisms, appearances in the liver simulating typical acute yellow atrophy are sometimes observed, but a critical study of such cases reveals some differences from the conditions observed in the so-called idiopathic acute atrophy.

The bacteriology of acute yellow atrophy has so far been very indefinite. This is easy to understand when one remembers that the liver is endowed with special functions for resisting microbic invasion from the alimentary canal. The Kupfer cells lining the sinusoids in the liver have, as we know, a powerful phagocytic action, and it is difficult to imagine that such a mass of highly specialized and actively functioning tissue as the liver presents is not intimately concerned with immunity processes in general. If anything, then, of a toxic nature acts on the liver, as is evidently the case in acute yellow atrophy, secondary microbic invasion is almost to be expected, and it becomes a matter of considerable difficulty to differentiate between a possible exciting agent of prime importance and a number of more or less harmless saprophytes, some of which may have entered the body after death. The isolation of the causal organism under these circumstances, if there be one, must not be expected to be an easy matter.

That infection of some kind apart from syphilis plays some part in the etiology of acute atrophy has long been held. In a large number of recorded cases some previous intestinal catarrh has been noted. The liver being so markedly affected in this disease, it has been justifiably held that the poison, whatever it may be, has been conveyed through the portal circulation.

In some cases *Bacillus coli* has been isolated *post mortem*; most observers, however, have regarded this as a condition without special significance and almost to be expected. Reichmann¹⁰ in 1908 isolated from the blood a sporulating Gram-negative bacillus, but as it has no special pathogenic power he did not regard the observation as important.

Apart from intestinal infection in a number of cases, so-called influenzal attacks are supposed to have played some part in the causation of the disease. Miller¹¹ in 1903 recorded a case in which active pulmonary tuberculosis was present, and was inclined to think that the tuberculous toxins had some causal effect. It may be noted, however, that there was at least a strong suspicion that this patient was syphilitic.

Finally, to apply these various suggestions to our present series of cases:

We have here five typical cases occurring together in a limited period; all have been syphilitic subjects, and all have been treated with salvarsan preparations *plus* mercury.

It is remarkable that though similar cases amounting to thousands have been treated by the same methods, such a complication as we have recently experienced has not been observed until now. This would seem to point to some other factor having been introduced. There is no evidence at present that the salvarsan has materially altered, at least in the last three years, and the syphilitic toxin and mercury factors may be taken as constant. Together with this, we have the observation that in each case there was found at the *post-mortem* examination microbic infection of a special type.

There would appear at least to be a *prima facie* case for regarding this infection as being the new factor which, acting on livers previously damaged by the syphilis, and possibly arsenic *plus* mercury, has completed the damage

* Readers interested may refer to the official memorandum published in the BRITISH MEDICAL JOURNAL (December 16th, 1916, p. 842), which contains a section dealing with this subject.

to the liver cells, and allowed autolysis of the tissue, which appears to be the essential liver change, to occur. Some such combination of circumstances might account for the rarity of the disease.

It is evident that a very considerable amount of work from a histological, chemical, and bacteriological standpoint is necessary in the cases already observed. I am indebted for assistance to Mr. P. C. Laws, M.A., in investigating the bacteriology of the cases.

It should be noted that neither clinically nor pathologically do the cases observed bear any close similarity to cases of spirochaetal jaundice.

Professor R. A. Bolam, who has seen some of the cases during life, is engaged with some others on the clinical side of the problem, and we hope in the near future to describe the cases in detail, and to give our conclusions, based on a more thorough study than other pressing work has permitted till now.

PERICARDIAL KNOCK.

BY

COLONEL S. MAYNARD SMITH, C.B., A.M.S.,
CONSULTING SURGEON, BRITISH EXPEDITIONARY FORCE.

THERE is a sound heard on auscultation in cases of penetrating wounds of the chest near the cardiac region which is unlike anything met with in civil practice. Its origin is, I believe, not yet established. The occurrence of this sound is now familiar to most of those who are dealing with these cases at the clearing stations. It is of the nature of a click, and varies from a faint sound heard by careful auscultation, to a noise which may be compared to that heard in the ear-piece of a telephone when the lever is moved up and down. It may be heard sometimes when standing at the foot of the patient's bed. Sometimes the patient is conscious of it, and on one occasion has himself called my attention to it. In nearly every case the sound disappears after forty-eight hours, although in one patient who was recovering from a chest wound without any complications the sound persisted for ten days. He was then sent to the base, and I have no further information about him. The sound has been, as a rule, most marked near the apex beat. It is usually double, corresponding to the heart sounds, and its intensity waxes and wanes with respiration, sometimes disappearing completely in full expiration. A distinct fremitus can be felt by the hand laid on the chest.

The first case in which I noted it was shown to me by Captain W. W. Rees, R.A.M.C. I then suggested that it was due to a shell fragment lodged where the pleura and pericardium are in contact. I thought this possible as I had previously heard a metallic rumbling sound in a case in which a shrapnel ball was seen by x-ray screen in the costo-diaphragmatic angle moving up and down with respiration. A skiagram in Captain Rees's case showed the fragment to be in the neighbourhood of the pericardium.

That this explanation was not the correct one was proved by the case of an officer shown to me by Lieut.-Colonel Newlands of the A.A.M.C. The characteristic sound could be heard when standing beside the patient's bed. The entry wound was outside the heart on the left side, and the track passed in the direction of the pericardium. Two days later a right-sided subphrenic abscess developed and was drained. The foreign body was found lying in the right side of the abscess cavity. An infected haemothorax was also drained. The patient died a few hours later, and at the autopsy a "sluggish" purulent pericarditis was present. This case showed clearly that the foreign body was not itself directly responsible for the sound.

In the next case I saw the foreign body was visible on the screen in the cardiac area. It moved continuously

with the heart beat, so that a skiagram showed only a blurred image. This patient died, and at the autopsy the pericardial surface was normal. There was no infection, exudate, or any sign of pericarditis. The cavity contained a few drops of blood-tinged serum due to the passage of the missile, which had traversed the pericardium and lodged in the interventricular septum. This case, as also several others in which the "knock" disappeared after twenty-four or forty-eight hours in patients who never had serious symptoms, shows that pericarditis is not the cause.

I may note in passing that the continuous movement of the foreign body shadow with the heart beat, as distinguished from an oscillatory movement at certain phases of the respiratory and cardiac rhythm, has indicated that the foreign body is actually in the heart wall or cavity.

It has been suggested that the sound is due to emphysema of the connective tissue of the mediastinum, but in one case the missile passed through the chest antero-posteriorly on the left side clear of the upper and outer margin of the heart. Moreover, a case has been reported by Captain Rees in which the sound was heard over the apex beat, which was normal in position. It was heard in systole and was loudest in full inspiration. The foreign body was seen on the x-ray screen moving with respiration, and in full inspiration there was an oscillatory movement communicated to it by the cardiac impulse. There was a clear space of some 2 in. between the heart shadow and that of the foreign body. The entry wound was over the lower end of the left scapula. Localization of the foreign body on anatomical cross-sections showed it to be lying behind the root of the left lung in close proximity to the rami bronchiales, and over 1 in. from the nearest point on the pericardium. The man's condition when he was sent to the base was very good.

The usual disappearance of the sound after a short period, and the absence of serious symptoms in many cases, suggests that it may be due to air in the interstitial connective tissue of the lung which is struck upon by the beats of the heart. Further records will doubtless throw more light on the subject.

A SIMPLE APPARATUS FOR NITROUS OXIDE-OXYGEN ANAESTHESIA.

By CAPTAIN A. S. WILSON, R.A.M.C.

THE infrequent use of nitrous oxide-oxygen as an anaesthetic for major operations in the British Expeditionary Force would make it appear that its very great advantages have not been fully realized. The rapid induction of anaesthesia and the immediate recovery are most important factors; with any general anaesthetic, the shorter the duration of its influence the better for the patient. Nitrous oxide is shorter than any other.

It is by far the most agreeable anaesthetic to take, and struggling and resistance are uncommon. Post-operative nausea and vomiting are hardly ever encountered; headache, restlessness, and bronchopneumonia are much less frequent sequelae than after ether or chloroform.

With reasonable skill and care on the part of the anaesthetist it is by far the safest general anaesthetic. Cyanosis under nitrous oxide, as under any other anaesthetic, is always a danger signal; when present, it is an indication that an insufficient proportion of oxygen is being supplied; such a mixture will never produce satisfactory relaxation, and usually results in muscular twitching and disturbed respiration. On the other hand, an excess of oxygen causes persistent movement, and prevents the onset of unconsciousness; such excess is frequently indicated by a red flush across the patient's forehead.

Desirable variations in the depth of anaesthesia to suit the requirements of different phases of an operation are much more rapidly and safely attained than with ether or chloroform. It is beyond the scope of this short paper to reiterate Crile's well-known findings on the physiological advantages of nitrous oxide as an anaesthetic.

Even after a prolonged administration, lasting up to two hours or more, the patient always completely recovers from the anaesthetic before leaving the operating table; this is invaluable when the number of post-operative cases is so large that it is impossible to provide a sister or trained orderly to stand by each patient till he is round

from the anaesthetic. During busy times at casualty clearing stations, when men are being rapidly evacuated, nitrous oxide anaesthesia allows of a patient being taken to the ambulance train immediately after operation.

Next to local anaesthesia it is the nearest to the ideal anaesthetic. In cases in which infiltration is insufficient nitrous oxide will be found a most useful and harmless adjunct; the analgesia which can be produced by hovering over the patient's face with the mask, supplying only a very gentle flow of nitrous oxide, is generally sufficient. It is not necessary to produce unconsciousness, merely a temporary "dissociation of ideas."

Nitrous oxide-oxygen is a perfectly suitable anaesthetic for any operation; there are no genuine contraindications.

It is advisable to employ the almost universal preliminary injection of omopon, scopolamine, and atropine, one ampoule omopon-scopolamine ($\frac{2}{3}$ grain omopon, $\frac{1}{15}$ grain scopolamine) being given an hour and a half before operation, and another half ampoule with $\frac{1}{15}$ to $\frac{1}{10}$ grain atropine sulphate half an hour before operation.

In thoracic surgery the paravertebral injection of novocain solution will greatly reduce the amount of anaesthetic required. In abdominal surgery, local infiltration—on the lines of Crile's anoci-association—combined with nitrous oxide, will result in perfect relaxation of the abdominal wall.

Those who have wished to employ this form of anaesthesia may have been discouraged by the difficulty and discomfort of administration with the ordinary apparatus supplied. The apparatus I have constructed may appeal to them; with it I have been able to maintain anaesthesia, lasting in some cases over two hours, with a minimum of difficulty.

The apparatus has been used in all cases described in the paper on thoracic surgery by Captains Lockwood and Nixon, in which local anaesthesia was found insufficient.

FIG. 1.—Apparatus fitted for working. The height of the cabinet is 2 ft. 6 in. and of the bracket 2 ft. 6 in.

The apparatus is assembled from materials available in any hospital, with the addition of a few minor items easily obtainable at a trifling cost.

It consists of a stand carrying two nitrous oxide cylinders (500 gallons each) and one 40-ft. oxygen cylinder in a vertical position, with a central upright for suspending the nitrous oxide gas bag, as shown in Fig. 1.

The nitrous oxide cylinders are connected direct to the gas bag by means of the delivery tube supplied for the ordinary foot stand. Gas passes from the bag through two lengths of "concertina" flexible tubing to the combined mixing chamber and face-piece of Hewitt's nitrous

oxide-oxygen apparatus. The supply of nitrous oxide is conveniently controlled by a straight hand key on the cylinder valve; the flow of oxygen is regulated by a Haldane's oxygen apparatus, which provides a pressure-reducing valve and a convenient mechanism for varying the amount of this gas as required. One of the four delivery tubes is connected to the oxygen inlet on the mixing chamber by a single length of concertina tubing. It is advisable to surround the upper end and connexions of the nitrous oxide cylinders with hot-water bottles to obviate the danger of freezing at the outlet. The usual precautions are necessary to prevent leaking at the connexions, the two lengths of concertina tubing are joined over a short piece of metal pipe. The gas bag should be covered; a small landing net (obtainable anywhere at very small cost) will be found useful for this purpose.

The construction of the stand will depend entirely on the materials and labour available. It is a very great advantage to have it mounted on four strong castors, as this renders it perfectly mobile.

The form of stand shown will be found convenient and simple. Two separate compartments are provided; that for the nitrous oxide cylinders is lined with cloth or other suitable material to retain the warmth provided by two hot-water bottles hanging inside. Both compartments have side doors with hinged top extensions, which facilitate the replacing of cylinders. There is a bracket on the top of the central upright for attaching the upper end of the nitrous oxide bag.

Some difficulty may be experienced with the differently shaped cylinders which have been supplied to the British Expeditionary Force recently; they are shorter and stouter than those which were formerly distributed. It is impossible to link two of these newer cylinders together by means of the ordinary delivery tube as stated above. Pending the distribution of a suitable connexion (which is contemplated) it will be found convenient to attach one of the ends of the delivery pipe to a nitrous oxide cylinder and fix a temporary gas-tight plug in the other arm of the tube.

With the above apparatus I have found it possible to maintain anaesthesia on about 120 gallons of nitrous oxide and 20 gallons of oxygen per hour.

FIG. 2.—Diagram of the arrangement of top; dimensions 12 in. from back to front and 13 in. from side to side.

ANAESTHETICS IN MILITARY HOSPITALS.

BY

THOMAS CLARKE, M.R.C.S., L.R.C.P. LOND.,

TEMPORARY LIEUTENANT R.A.M.C.;

ANAESTHETIST, THE LORD DERBY WAR HOSPITAL; ANAESTHETIST, VICTORIA HOSPITAL, BURNLEY.

HAVING now been administering anaesthetics for several years in hospital and private practice and daily for the last seven months at the Lord Derby War Hospital, Warrington, with 3,000 beds in the summer and 2,500 in winter, the following is my experience:

The patient is given as a preliminary morphine $\frac{1}{4}$ grain, atropine $\frac{1}{15}$ grain, half an hour before the operation. The preliminary injection of morphine and atropine is not only followed by less secretion of mucus and a quieter anaesthesia, but the patient usually sleeps for an hour or two after the operation, thus causing very much less trouble to the nursing staff—a great advantage in a busy hospital.

The anaesthetic mostly used by me is ether, preceded by chloroform. I use two separate masks, one covered with a layer of lint for chloroform and the other with two layers of lint for ether. By using two separate masks the danger of giving a mixture of unknown strength is avoided, and I almost invariably use the open ether drop method on a Schimmelbusch's mask.

At the beginning of the administration I drop about one drachm of chloroform slowly on the mask, holding it an inch or so from the patient's face and quietly talking to him, or in nervous cases getting him to count. During this time the mask is lowered, until in about a minute

or so it is resting on the face. I then replace it by the ether mask and quickly drop on ether till the lint is saturated. Next I place a towel, two or three folds, over the mask to increase the concentration, leaving sufficient space to apply the anaesthetic continuously. By this method I rarely get any struggling and often not the slightest movement on the part of the patient, who is generally ready for the operator in three or four minutes. This ensures the maximum degree of safety, is certainly very quick, and preferable to beginning with ether alone. Patients all agree that the chloroform is pleasanter and less irritating. For instance, it is quite the rule for those men who have had both anaesthetics to tell me that they prefer chloroform. The average quantity of anaesthetic for an operation of half an hour is 2 drachms of chloroform, 3 oz. of ether. Occasionally it is very difficult to keep some of these young subjects under with the ether drop method alone, especially in abdominal cases, and it may be necessary to resort to a little chloroform or C.E. mixture for a short time and then resume the ether.

In my private and previous hospital experience I have administered nearly three thousand anaesthetics, the bulk by the method outlined, and have not had one fatal case or any serious difficulty.

In my early days I was taught to give ether by the Clover method, but now rarely use it, for to my mind the ether drop method is very much better, in that the patients very rarely get cyanosed, have less trouble with mucus, a quieter anaesthesia, and less sickness after the operation.

I have also introduced a Shipway's warm ether apparatus, and, in conjunction with my own methods, find it very useful in cases requiring prolonged administration, in that it conserves the body heat of the patient, and is also a saving of the anaesthetic.

Ethyl chloride and nitrous oxide have proved quite satisfactory for patients requiring a short anaesthesia such as for incisions and manipulation of joints.

I find, after giving anaesthetics daily in a military hospital, that it is quite different from administering them in a general hospital in peace. In the latter it is the exception to have a strong, healthy young man to anaesthetize, the majority of cases being women and children or men usually with a definite organic or inflammatory lesion and often well prepared for an operation. Military cases are frequently robust young men who have lived an outdoor life for varying periods and many of them have been in the trenches and subject to war strain and nervous exhaustion. I have also found that men suffering from shell shock require much more anaesthetic than other men and have a greater tendency to excitement whilst going under. In these cases a little encouraging suggestion during the first stage of anaesthesia not only helps during the administration, but is also beneficial afterwards. At first I was inclined to attribute this to the mode of living, which made them difficult to anaesthetize, but I am now convinced there is a nervous element to contend with. It is impossible in many cases to judge by the appearance of the men how they are likely to behave under an anaesthetic. Some of the apparently quiet and sickly-looking men take a large quantity of anaesthetic and become troublesome with excitement, whereas some of the rough-looking and vigorous need very little.

In a short note Marcus W. Lyon (*Anatomical Record*, Philadelphia, 1917, xiii) records the case of a woman, aged 41 years, whose right kidney was absent, the left being hypertrophied. The right ureter was connected with the urinary bladder and contained a little calculous debris. The adrenals on both sides were in their normal positions. There was only one Fallopian tube and one ovary. The interest of the case is that the patient's maternal grandmother had been operated upon for some abdominal condition and that one kidney—it is not stated which—was found to be absent.

SURGEON B. J. LLOYD, of the United States Public Health Service, sanitary inspector under the Bureau of Medicine, in a recent report states that at Bremerton, Washington, where the Paget Sound navy yard is situated, and at Seattle, the neighbourhood swarms with prostitutes from all parts of the country. He recommends that the Navy Department should procure the enactment of a law declaring a general district, one hundred miles in diameter, surrounding every military and naval reservation. From this all undesirable persons should be excluded, and the most objectionable should be interned.

ON THE TREATMENT OF GUNSHOT WOUNDS WITH A SOLUTION OF SOAP AND WATER AND PRIMARY SUTURE.

BY

CAPTAIN J. B. HAYCRAFT, M.B.EDIN., R.A.M.C.,
SURGICAL SPECIALIST, No. — CASUALTY CLEARING STATION.

At the suggestion of Colonel Cuthbert Wallace, consulting surgeon to our army, I commenced treating as many gunshot wounds as possible by primary suture, using instead of an antiseptic a solution of soap and water.

The solution used has been of the strength 1 in 40. Pure *sapo durus* (1 part), obtained in blocks, is cut into shavings and dissolved in hot water (20 parts) which has been previously boiled. When required for use the solution is mixed with an equal volume of sterile water.

OPERATIVE TECHNIQUE.

Superficial Wounds.

Superficial wounds are completely excised and soap solution well rubbed into the surface; they are then stitched up.

Single Penetrating Wounds.

The skin wound is completely excised, the exposed surface of the wound in the muscle cut away, and the track of the missile laid thoroughly open. The wound being held widely open with retractors, the surface of the track is cut away all round, *from the inside*, with scissors until all damaged muscle, as far as it is visible to the naked eye, is removed. Foreign bodies, clothing, or any small, loose fragments of bone, are removed, all bleeding points ligatured, and the whole wound thoroughly swabbed out with soap solution. Muscles and fasciae are closed with catgut and the skin sutured.

If the metal has passed almost through the thickness of a limb, it is removed by a counter incision and the wound converted into a seton wound.

Seton Wounds.

Both entrance and exit wounds are treated as above, and it is generally possible in this manner to expose and excise the whole track, one half from each incision. In cases in which this has been impossible for anatomical reasons the centre of the track has been well rubbed with gauze and soap.

If it only involved the division of a thin layer of muscle, the entrance and exit wounds were directly connected, laying open freely the whole track, which could then be dealt with. If there is gross loss of muscular tissue so that the ends cannot be approximated, or if a large dead space is left, the skin is sutured over the wound and a very small split rubber tube introduced for twenty-four to forty-eight hours.

In cases in which it is difficult to approximate the skin edges without undue tension one or more incisions may be made down to the deep fascia parallel to and at some distance from the wound. This occurs most often in the forearm and lower part of the leg.

Amputations.

Amputations have been completely stitched up with a very small split tube introduced into one corner for twenty-four hours. Penetrating wounds of knee-joints have been completely excised down to the synovial membrane, the joint well irrigated with soap solution, and the wound closed in layers.

Effect of the Soap Solution.

The effect of the soap solution on the wound appears to be haemostatic. Instruments, needles, etc., tend to become somewhat slippery—a slight disadvantage.

RESULTS.

During the last four months all cases in which it was possible have been treated by this method, but during one period of pressure it was impossible.

Patients have been kept on an average for ten days and then evacuated by barge to one general hospital, where they have been seen by Colonel Cuthbert Wallace, and reports on progress have been given to me by him and sent by the medical officers of that hospital.

CHART 1.—O, Operation. S, All stitches removed.

CHART 3.—O, Operation. S, All stitches removed.

CHART 2.—O, Operation. S, All stitches removed.

CHART 4.—O, Operation. R, One stitch removed. S, All stitches removed.

In this way it has been possible to follow the early history of all patients except a few who were unavoidably lost sight of during the period of pressure. The total number of cases was 116.

Radius and ulna ...	1	1	0	0	0
Radius ...	5	4	1	0	0
Ulna ...	6	4	1	1	0
Total...	38	23	5	2	3

*One case was a partial fracture in which a piece of shell had passed through the shaft of the femur about the middle without producing complete fracture.

Out of a total of 98 cases in which the result was observed 91 eventually healed and 7 failed altogether.

Out of 38 cases of compound fracture, 33 eventually healed and 2 failed.

A considerable proportion of cases healed dry without any discharge. In some there was a little oozing or slight superficial suppuration, necessitating removal of one or two stitches before they healed.

A few cases became very swollen, red and shiny, about the second day, simulating acute cellulitis. The temperature rose to 102.3, but the pulse as a rule remained below 100. After a day or two the swelling began to subside, redness disappeared, and the skin became crinkled, due to diminution of subcutaneous oedema. These cases may cause alarm at first, but it is rarely necessary to remove any stitches. The pulse-rate appears to be the best guide.

In some cases in which the wound was gangrenous before operation a brownish discoloration appeared around the wound, and the part might even become tympanic. On removal of one or two stitches gas and offensive discharge escaped, and the infection as a rule subsided.

Four temperature charts are appended. Chart 1, a case of excision of elbow-joint, and Chart 2, an amputation of leg, followed a perfectly normal course and healed by first intention.

Chart 3 was a case of compound fracture of humerus with an opening into the elbow-joint. On the second day the whole elbow was very red, swollen, and shiny in appearance. It all subsided, and the wound healed by first intention.

Chart 4 shows a case of compound fracture of the femur. It was a severe fracture, with a large exit wound, in order to close which tension incisions had to be made. For the first six days his temperature rose at night and the pulse-rate caused apprehension, but on removal of one stitch on the sixth day, evacuating a small collection of turbid fluid under the skin, it gradually subsided and the wound healed.

CONCLUSIONS.

1. Soap solution easily permeates and comes into contact with the whole surface of the wound. It acts as a mechanical cleansing agent, washing away all débris.

2. Complete excision of a wound leaving an aseptic surface is possible only in superficial wounds and in superficial muscular wounds. It is impracticable in deep penetrating wounds, compound fractures, etc., on anatomical grounds, and it would also entail a much freer removal of tissue, which may impair future functional result. These latter cases, when treated by soap solution and primary suture, heal better than if an antiseptic such as enzol or bipp had been used. It follows from this that the tissues themselves are able to deal successfully with any infection which is left behind without the aid of any antiseptic. This point is particularly exemplified by those cases in which there is at first an intense local reaction following on the operation; it subsides as the tissues gain the upper hand.

3. Success depends on getting cases within a few hours of being wounded, before infective processes have spread far into the adjacent muscles, on the thorough removal of dead or grossly damaged tissues, and on the localization by x rays and removal of any foreign body that may be present.

4. Compound fractures of the upper extremity practically always do well; only three cases of fracture of the femur have been thus treated, and of these two were successful, but the number is too small to warrant a definite opinion. It is necessarily the most severe type of case one has to deal with, but the results of those cases have been distinctly encouraging.

5. The advantages of primary suture are obvious: (a) Easy, rapid, and painless dressings; (b) time is saved for everybody once the patient has left the operating theatre; (c) it is economical. The time taken in the operating theatre is, however, considerably longer, and this generally forbids the use of the method when the pressure of work is high.

6. One of the most important points is that no severe injury which has been stitched up should be evacuated for at least a week—first, because movement may just turn the balance during the early days of local reaction when the tissues are getting the upper hand and cause failure, and, secondly, because when it is very difficult to decide whether the case should be opened up or not the operator himself is in a much better position to judge what is likely to be taking place inside the wound he has sewn up than some one else who gets the case later; consequently stitches remain in which may otherwise be taken out perhaps through no fault of any one.

7. No opinion can be given as to the ultimate functional result as to bony union and action of muscles.

In those cases in which primary suture has been out of the question owing to gross loss of tissue, after the usual operative procedure I have used a soap pack after the manner of the salt pack. It has been left in as a rule for five to seven days, and when taken out left a beautifully healthy wound.

Acknowledgements.—I wish to express my indebtedness to Colonel Cuthbert Wallace, C.M.G., for much help and encouragement, and to Lieut.-Colonel D. O. Hyde, D.S.O., R.A.M.C., for kindly allowing me to keep these cases and to publish notes on them.

A SEROLOGICAL INVESTIGATION OF VINCENT'S ANGINA.

BY

FRANK E. TAYLOR, M.A., M.D., M.Sc., F.R.C.S.,
M.R.C.P., D.P.H.,

LECTURER ON BACTERIOLOGY, UNIVERSITY OF LONDON, KING'S
COLLEGE,

AND

W. H. MCKINSTRY, M.D., D.P.H.,

TEMPORARY CAPTAIN R.A.M.C.,

PATHOLOGIST AND BACTERIOLOGIST, QUEEN ALEXANDRA MILITARY
HOSPITAL, MILLBANK.

Infective disorders of the pharynx include a great variety of different conditions—ulcerative, membranous, ulcero-membranous, and septic—due to different micro-organisms, so that for their accurate differential diagnosis careful bacteriological investigations are necessary.

The nature of these investigations will depend on the clinical appearance which the lesions present. Thus, in membranous inflammations cultures on Loeffler's blood

serum would reveal the presence or absence of the Klebs-Loeffler bacillus; in ulcero-membranous conditions the microscopic examination of properly prepared stained films would show the spirochaete and *B. fusiformis* of Vincent; a positive Wassermann reaction would prove the nature of ulcerative conditions to be syphilitic, whilst cultures and films showing streptococci and staphylococci would be obtained in pyogenic infections.

The value of the Wassermann reaction in the differentiation of these various conditions cannot be denied, being positive in syphilitic affections of the pharynx and negative in all others, with the exception of the angina of scarlet fever, which presents sufficiently characteristic symptoms not to lead to confusion, and is not further considered here.

This opinion, however, which is based on the careful bacteriological examination of several hundred cases of sore throat at the Queen Alexandra Military Hospital, is quite at variance with the views expressed in several contributions scattered through the literature of the subject, in which it is maintained that in uncomplicated cases of Vincent's angina the Wassermann reaction is often found to be positive. Thus, StClair Thomson¹ states that—

From syphilis the differentiation—(of Vincent's angina)—is . . . difficult, as both fusiform bacilli and spirilla may be found in a cover-glass preparation from a tertiary ulcer, and also because, apart from concomitant syphilis, the Wassermann reaction may be positive. In more than one case I have seen a suspected Vincent's angina reveal its true nature by the evolution of a coppery rash or other specific stigmata.

The value of this statement is largely invalidated by the vagueness of the diagnosis of the Vincent's angina which was merely suspected. The diagnosis should, of course, have been definitely made by bacteriological examination. Still, allowing that the cases were really Vincent's angina, they would merely confirm Sobernheim's and Weinstein's findings that syphilitic and fusospirillary pharyngitis may coexist, and support our own conclusions that Vincent's angina may occur in subjects with latent syphilis. Bowman,² again, considers "that the disease may be confused with syphilis, and Vincent's angina may be superimposed upon a syphilitic or diphtheritic infection of the mouth and throat." Nevertheless, he found that the Wassermann reaction had always been negative in the uncomplicated cases of Vincent's angina seen by him.

Bouty³ also, describing his experiences of Vincent's angina among the troops in France during the last two years, states that "the Wassermann reaction in Vincent's angina is negative," but the evidence upon which this statement is made is not given. This agrees with the findings of Campbell and Dyas,⁴ who state that "a positive Wassermann reaction does not exclude Vincent's angina, nor does the fact that a mouth lesion clears up quickly under arsenic exclude syphilis." In cases of Vincent's angina with no syphilitic history, however, the Wassermann reaction is always negative.

Ehrlich⁵ in 1910 called attention to the value of intravenous injections of salvarsan in Vincent's angina, and recorded the rapid healing within a few days of the lesions of this disease. Gerber⁶ in the same year described a case successfully treated in this way, stating that the Wassermann reaction was weakly positive, and that he had also found it so in a previous case; he considered, therefore, that he could not definitely exclude syphilitic infection. Gerber⁷ also quotes Much as having obtained positive Wassermann reactions in this condition. Much's⁸ own statement made in 1908 is that in one other case of Vincent's angina multitudes of non-specific spirochaetes were found in the tonsil. Lues was excluded, but on what grounds is not stated. The examination of the blood by the complement fixation method, which was undertaken during the febrile stage of the disease, gave a strongly positive reaction. Fourteen days afterwards, when the patient had recovered from the angina, the reaction was found to be negative.

Sobernheim's⁹ name is constantly encountered in the literature of the subject as supplying the most definite evidence of the finding of a positive Wassermann reaction in Vincent's angina. His evidence rests solely on three cases, and a critical examination of these shows the flimsy basis on which his statement rests.

In the first case the patient presented the symptoms of secondary syphilis—typical exanthem, anal condylomata, and mucous plaques on the tonsil. While antisyphilitic treatment was being carried out a deep greyish-yellow coated ulcer, with

all the characteristics of Vincent's angina, developed. *B. fusiformis*, *Spirochaeta vincenti*, and *Spirochaeta pallida* were observed by dark-ground illumination. Antisyphilitic treatment was suspended, serological examination of the blood gave a positive result, and after some days the ulcer healed spontaneously.

The second case was a youth of 17, who complained of pain in the neck and difficulty in swallowing. The left tonsil was red and swollen, its upper pole being covered with a smeary exudation. The cervical glands were enlarged, but not tender. In stained film preparations *B. fusiformis* and spirochaetes were present in enormous numbers, and the diagnosis of Vincent's angina was made. The Wassermann reaction was completely positive. Potassium chlorate lozenges were ordered, and healing was complete in eight days.

The third case was a young woman of 18, in whom the diagnosis of Vincent's angina was made from the condition of the tonsil and the whole course of the illness. The Wassermann reaction was negative. A few days later an ulcer of the tonsil appeared, which rapidly cleared up without specific treatment. Mucous plaques developed later on both tonsils, and the patient was then placed on antisyphilitic treatment.

Sobornheim concludes that great caution must be exercised in applying the Wassermann reaction to the differential diagnosis of lues and Vincent's angina.

In the first and third of these cases it is obvious that the syphilis and the Vincent's angina were merely concurrent infections, and that in the second case latent syphilis, either congenital or acquired, could not be excluded with certainty.

Weinstein,¹⁰ in discussing the value of the Wassermann reaction in rhino-laryngological practice, stated that in cases of Vincent's angina the ulceration of the tonsil may sometimes appear to be syphilitic, and that neither the clinical appearances nor the microscopic findings are sufficient to establish a definite diagnosis with certainty. In such cases he states that he employed the Wassermann reaction with good results, and gives his experience of four cases:

A woman of 24, suspected to being syphilitic, presented the typical appearances of Vincent's angina, with an immense number of fusiform bacilli and *Spirochaeta buccalis*. The Wassermann sero-diagnostic test was completely negative. In two other persons suffering from Vincent's angina, with the characteristic micro-organisms present, a history suggestive of syphilis was obtained, and was confirmed in both cases by the Wassermann reaction. In the fourth case of angina with a doubtful syphilitic history, in which *B. fusiformis*, *Spirochaeta buccalis*, and *Spirochaeta dentium* were present in large numbers, the sero-diagnostic test was negative.

Saverio,¹¹ discussing Vincent's angina and syphilis, considers from the cases cited above that the presence of numerous Vincent organisms in the exudation of cases of angina does not as a necessary consequence produce any deviation of complement, and that until such important problems have received sufficient light new parallel studies must be made—on the one hand to establish the pathogenic value of the spirochaetes commonly found in Vincent's angina, and, on the other hand, to accumulate sufficiently numerous cases of similar forms of angina in which the sero-diagnosis has been made. If a certain diagnosis cannot be made, he holds that the hypothesis of Vincent's angina in syphilitic subjects is the most probable.

It is to the latter suggestion of Saverio's that we have directed our attention. At the Queen Alexandra Military Hospital we have recently had occasion to examine bacteriologically more than 300 cases of fuso-spirillary infection, and about half this number were typical cases of Vincent's angina verified by bacteriological findings.^{12, 13} From this number we have taken at random, and with no more selection than mere convenience demanded, 55 cases, and had the blood tested by the Wassermann reaction, performed either by one of us (F. E. T.) by the method recently described,¹⁴ or at the laboratories of the Rochester Row Military Hospital.

In all of these cases, with but two exceptions, no fixation of complement could be observed. The histories of these two cases, in which a positive Wassermann reaction was obtained, are as follows:

CASE I.

Pte. G., Australian Imperial Force, attended the laboratory on December 14th, 1916, for a sore throat which had troubled him for a week. A superficial ulcer was seen on the right tonsil, and the margins of both upper and lower gums were ulcerated and covered with a soft, creamy exudate. The lymphatic glands at the right angle of the jaw were swollen and tender. The ulcers on the tonsil and gums bled when touched lightly, and smears from these parts showed numerous fusiform

bacilli and spirochaetes. The gums and tonsil were treated daily and by December 20th the latter was quite healed. The patient continued to attend for treatment of his gums, and on December 24th a sluggish-looking ulcer was noticed on his left tonsil. Smears from this ulcer presented microscopically a typical picture of the organisms of Vincent's angina, but it was noticed that the glands at the angle of the jaw were not enlarged and the ulcer did not bleed when touched. The Wassermann reaction was positive. On cross-examination the patient admitted that he had contracted syphilis in Australia, having had a primary chancre ten years previously for which he was treated successfully; he remained free from secondary symptoms and had had no further syphilitic manifestations up to date.

CASE II.

Pte. J., Australian Imperial Force, attended for a sore throat which had troubled him for a month. There was a deep ulcer filled with a yellowish-white exudate on the left tonsil, and the upper and lower gums were ulcerated. The ulcers on the tonsil and gums bled when lightly touched, and smears when examined microscopically showed the usual picture of the organisms of Vincent's angina. The lymphatic glands at the left angle of the jaw were enlarged and tender. As we were making a serological investigation of Vincent's angina at this time a sample of the patient's blood was taken for examination and gave a positive Wassermann reaction. The result was communicated and explained to the patient, who then admitted having had a chancre ten years ago, when he was treated by a herbalist for three months with medicine and ointment for the sore. No secondary or further symptoms of the disease had been noticed. He was married, but had had no children. The throat and gums were treated on the lines we had adopted for fuso-spirillary ulcerations. The throat had healed in a week, and the gums about three weeks later. This case, from its clinical characteristics and microscopical findings, was obviously one of fuso-spirillary ulceration in a subject with latent syphilis.

These two cases, then, were the only ones out of a total of 55 cases of Vincent's angina examined by the Wassermann test in which the reaction was positive; the remaining 53 cases were quite negative. The positive character of the reaction in the two cases admits of a ready explanation, and was not due to the fuso spirillary infection of Vincent. In both cases the condition was one of Vincent's angina in a subject of latent syphilis.

As a result of this investigation and of a careful and critical consideration of cases recorded in the literature we have come to the conclusion that the prevailing belief in the occurrence of a positive Wassermann reaction in Vincent's angina has no foundation in fact, and that the two conditions can be differentiated with absolute certainty by the application of bacteriological and serological methods; and that when the complement-fixation test of Wassermann is positive in cases of Vincent's angina, then a double infection exists, either as a coincident syphilitic and Vincent's infection or as the occurrence of Vincent's angina in the subject of latent syphilis.

A PREPARATORY institution for the school of naval medicine has been established temporarily in connexion with the University of Bordeaux. Its object is to give the first year of medical training to young men intending to adopt the career of naval or colonial surgeon.

THE French Food Minister, M. Victor Boret, who worked in maltings and in a shipbroker's office in this country before joining his father as a corn merchant in France, takes a sanguine view of the food position of that country. There is, he says, enough meat, potatoes, and corn, except oats, if there is no waste. In Germany there is, he believes, a total want of fats, oil, tea and coffee, and so great a shortage of foods that the people are underfed. There has recently been some difficulty about bread in Paris, owing to transport delays due to the bad weather and severe snowstorms, but arrangements have been made which it is believed will ensure an even distribution of flour among the bakers.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A NOTE ON SKIN GRAFTING.

Two instances of skin grafting in my practice are worthy of notice, especially by the general practitioner.

In both cases there was an extensive raw surface, one over the whole front of the lower leg in a man of 65, the other in a virile old man of 82 over the whole area of the scapula.

I have nothing to suggest as to method, but, as far as I know, the source of the grafts is novel. The foreskin of a circumcised infant was utilized in each case. At least two hours elapsed after the circumcision before the grafts were placed *in situ*; they were kept in the meantime in a bottle of normal saline. The wounds were both clean and fairly free from discharge. The grafting skin was scraped and cut into small pieces about one-eighth of an inch square, applied to the wound, covered with oilskin, and bandaged lightly. Two days were allowed to elapse, and it was then found that six out of seven grafts had taken in each case.

The points of interest are (1) the source of the grafts, (2) the utilizing of a waste product, and (3) the length of time between the taking and planting of the grafts.

Wednesbury.

BILATERAL TWISTED OVARIAN TUMOURS.

On opening the abdomen of a patient to deal with, as I thought, a twisted ovarian tumour, I was surprised to find that the condition was bilateral there being an ovarian tumour the size of a fetal head on the left side, and one somewhat larger on the right. As the patient had been ill about a fortnight before I saw her, both were almost gangrenous and adherent to everything round about. With patience both were isolated and removed, and as the vermiform appendix was closely involved in adhesions to the tumour of the right side, it also was removed. Owing to the condition of the tumours drainage was necessary for some days, but the recovery of the patient was uneventful.

JOHN ARMSTRONG, M.D., R.U.I., F.R.C.S.I.

Ballymena Cottage Hospital.

A CASE OF SEPTICAEMIA DUE TO INFECTION BY *BACILLUS DYSENTERIAE* SHIGA.

The following case is of special interest in presenting several abnormal clinical and pathological features:

Driver A. B., aged 21, after two years' home service went to the East. On July 22nd diarrhoea is said to have commenced—twelve to fourteen stools daily. The patient stated that he had headache from onset, but no mention was made of abdominal pain or tenderness. On July 27th he was admitted into a dysentery ward of the military hospital at Malta, under my care. He was then exhausted and collapsed, with sordes on teeth and lips, furred tongue, extreme thirst, constant headache, marked restlessness, and incontinence of urine and faeces. The temperature was 99°, and the pulse 84. His appearance suggested a severe typhoid condition, so much so that, although admitted as a suspected dysentery, antidyenteric serum was withheld pending the pathological examination of the stools. He could answer questions and remained quite rational for the first twenty-four hours. No enlargement of liver or spleen was detected, and no abdominal pain or tenderness elicited; there was no exanthem and nothing abnormal in heart or lungs.

The stools, which were very frequent, consisted of fluid faecal matter mingled with blood in considerable quantity. Their glairy appearance suggested amoebic dysentery, but no animal parasites were found by the protozoologist. Tenesmus and straining were absent, and the patient never complained of any abdominal discomfort.

On July 28th he was more drowsy, becoming semi-conscious and incoherent at times. The restlessness had increased—frequently tried to get out of bed—but he took fluids well, and the pulse had improved. The temperature once reached 100.2° (its maximum), otherwise it remained about 99° till the day of death, when it fell to 97.4°. The stools now consisted almost entirely of pure, bright blood. His condition steadily became worse, and on July 29th, as he was presenting a picture of increasing septicaemia resembling the typhoid state, blood was taken from the median basilic vein for pathological examination. By this time the pathologists had reported the stool culture to be negative to *Bacillus dysenteriae* Shiga.

On consultation, the view was expressed that the case was probably a fulminating Shiga dysentery, stress being laid on the carinated abdomen associated with the marked toxæmia. The administration of antidyenteric serum was advised, and

60 c.cm. immediately injected subcutaneously; it was rapidly absorbed. This dose was repeated next day, when it was found that the patient's blood—which had been sown in bile and incubated for twenty-four hours—gave a profuse, pure growth of the Shiga bacillus, and also an agglutination which pointed strongly to Shiga infection. Still no *Bacillus dysenteriae* Shiga had been found in the stools.

The patient's condition steadily became worse, and, in spite of frequent saline infusions and other stimulative treatment, he died at 8 p.m. on July 30th, within three days of admission.

The *post mortem* examination showed extensive disease of the large intestine. The whole of the mucous membrane from the ileo-caecal valve down to the anus was intensely congested, being studded throughout with minute superficial ulcers. The whole appearance showed an exceedingly rapid and fatal infection with *Bacillus dysenteriae* Shiga, which was isolated from scrapings taken from the mucous membrane of the lower bowel. Nothing abnormal was found in the small intestine.

The points of special interest in the case are:

1. The rapid progress of the disease, producing a profound toxæmia caused by the septicaemia.
2. The atypical temperature chart.
3. The marked cerebral symptoms as compared with the clear mental condition exhibited in ordinary acute dysentery cases.
4. The absence of any abdominal pain, tenderness, straining, or tenesmus.
5. The fact that the Shiga bacillus was not isolated from the stools during life, whereas, in the great majority of acute bacillary stools examined during the last two and a half years at this military hospital, positive results have been obtained.

6. Lastly, and perhaps most interesting, the fact that a pure culture of the Shiga bacillus was grown from the patient's venous blood. Only rarely has it been found possible to isolate the *Bacillus dysenteriae* Shiga from the blood, this being the first occasion at the hospital, and, so far, only a few cases have been reported by workers in other laboratories.

I wish to tender my grateful thanks to Captain Shields, R.A.M.C., O.F.C. Laboratory, and to Dr. Ada McLaren, for their kind collaboration, and also to the O.C., Lieut.-Colonel G. B. Price, R.A.M.C., for permission to publish the case.

C. MURIEL ASTLEY MAER, att. R.A.M.C.

Rebicus.

CONDUCTION OF THE NERVE IMPULSE.

In 1914 Dr. KEITH LUCAS of Cambridge delivered seven Page May Memorial lectures at University College, London, but they had not been completely written out at the time of his untimely death in an aeroplane accident. His co-worker, Dr. ADRIAN, has therefore, with the modest devotion of a pupil, finished the last labours of a great physiologist, who since the beginning of the war had applied all his inventive genius to solving the practical problems of aviation, and whose death, as will be disclosed later, is as great a loss to flying as to physiology. The result is a volume with the title *The Conduction of the Nervous Impulse*.¹

The object of the lectures was to discuss how a nerve conducts the nervous impulse and how far the phenomena of conduction in a peripheral nerve can be made the basis of the understanding of conduction in the central nervous system. The impulse in a nerve of a nerve-muscle preparation is followed by a refractory period, during which the nerve is unable to respond to a second stimulus; this is due to a defect both of excitability and of conductivity. With the return of excitability the nerve becomes more excitable than when at rest, and the supernormal phase explains the phenomenon of summation—namely, that when a single impulse fails a repetition succeeds, provided that it is so timed as to fall within the supernormal phase left by its predecessor. After the demonstration that summation and apparent inhibition—the two most important phenomena of reflex conduction—can be reproduced in the isolated nerve-muscle preparation, the phenomena of these processes are applied to the central nervous system in the chapter on central inhibition, which Dr.

¹ *The Conduction of the Nervous Impulse*. By the late Keith Lucas, Sc.D., F.R.S., Fellow and Lecturer of Trinity College, Cambridge. Revised by E. D. Adrian, M.B., M.R.C.P., Fellow of Trinity College, Cambridge. Monographs on Physiology. Edited by E. H. Starling, M.D., F.R.S. London: Longmans, Green and Co. 1917. (Med. 8vo, pp. 102; 22 figures. 5s. net.)

Adrian has supplied with some hesitation owing to uncertainty as to how far the late Dr. Keith Lucas would have wished to enter into the speculation necessarily involved in the discussion of this subject. As Professor Starling says in his sympathetic preface, Keith Lucas's work is for all time, and will serve as a sure vantage ground for future investigators.

MEDICINE IN THE DARK AGES.

DR. CHARLES SINGER'S *Review of the Medical Literature of the Dark Ages*² is a scholarly piece of work for which all students of the history of medicine should be grateful. He dates the new birth of medicine in Western Europe from the translations of the so-called Arabian writers, which began to be well known in the second half of the twelfth century. For at least three hundred years Latin translations from Arabic versions and commentaries on Aristotle, Galen, and other Greek writers were the basis of such scientific knowledge as there was.

The true mediæval period of medicine began somewhere about 1150, while the dark age began at the death of Bede (673-735). The medical writings produced in Western Europe during the four centuries following that event fall under one of three heads—vernacular, Latin extra-Salernitan, and Salernitan. A brief account of each of these groups is given. Vernacular medicine in Europe before the twelfth century is confined to Anglo-Saxon texts. The characteristic features of our native medical literature are wide knowledge of herbs and simplicity of pharmaceutical processes. There are no anatomical descriptions, and no attempt is made to separate diseases from symptoms. Salernitan medicine deeply influenced some of the Anglo-Saxon literature, but the two have a common ancestor in Greek and Roman medicine.

Dr. Singer's search in the dust of forgotten lore has brought to light a new text of about 1110 which is an encyclopaedia of scientific knowledge of the twelfth century. The MS., which was found in St. John's College, Oxford, is of folio size, and consists of 177 parchment leaves, the text being illustrated by a large number of coloured diagrams and a few pen and ink drawings. Among the contents are sections on lucky and unlucky days, a table of consanguinity, astronomical tables and calculations, etymologies, rules of grammar and prosody, with other miscellaneous matter. To the medical historian the most interesting part is a compendium of medicine consisting of chapters on the constitution of the body from the four humours, the regimen of the four temperaments, blood letting, the prognostication of life and death, a glossary of herbs, a table of weights and measures, recipes for electuaries and for plasters, an Anglo-Saxon charm to stop nose-bleeding, the relation of fevers to the humours, the principles of pathology, panaceas, an alphabetical list of remedies with the diseases for which they are suitable, and a list of diseases with the appropriate remedies. Dr. Singer publishes the Latin text, and very "doggy and mediæval" (to use a phrase of Sir Clifford Allbutt's) it is; for the convenience of the reader he has broken up the sections into paragraphs and has supplied headings. As the text is in many places defective he has filled in gaps and furnished necessary elucidations. He also gives partial translations of some of the more important passages. Dr. Singer has no doubt that the writer of the MS. was a Saxon, not a Norman. He says that the treatment of the theoretical aspect of medicine in the work, absurd as it is, marks a real advance on what had gone before. It shows signs that the human intellect, which had reached its nadir in or about the tenth century, was already in the ascendant, and preparing for a brighter future.

The same volume of *Proceedings* of the Royal Society of Medicine contains a note by Dr. Singer on the figures of the MS. of the *Inventorium seu collectorium in parte Chirurgiali Medicinæ* or *Grande Chirurgie* of Guy de Chauliac. It was written by Jean Tourtier, master in surgery, for presentation to the Duke of Bedford, and can therefore be dated between 1420, when the Duke became Regent of France, and 1435, when he died. Scattered through the volume are eight miniatures showing an anatomical demonstration, and surgical scenes such as

opening of abscesses, stitching and dressing of wounds, blood-letting, and so forth. All these are reproduced. There are also some rough drawings of surgical instruments.

NOTES ON BOOKS.

THE publication of the twenty-eighth issue of *Burdett's Hospitals and Charities*³ has been unavoidably delayed owing to difficulties due to the war, which are particularly heavy in the case of an elaborate and exhaustive reference book of this kind. Despite the war, every effort has been made to keep the work accurate and up to date. So far as possible, those institutions are indicated which have supplied accommodation for the reception of the sick and wounded from the war. It has, however, been found impracticable to separate the financial results of the normal from the abnormal activities of permanent charities under war conditions, and the total income and expenditure only have been indicated in the accounts. This year's issue includes for the first time the names of military convalescent camp hospitals, and the tables relating to the hospitals of the United States, Canada, Australasia, and India have been remodelled. The opening chapters give the usual comprehensive survey of the volume of charity, of hospital finances and new construction, and of many other matters of particular interest to the world of charity. As in the previous volume, the index is placed at the end of the first 156 pages of literary matter, thus bringing it into direct contact with the classified directory of institutions which occupies the greater part of the volume. Sir HENRY BURDETT is to be congratulated on the continued excellence of this indispensable year-book of philanthropy and hospitals, and we hope that he may be successful in his quest for a competent successor in the editorship, to which he once more makes allusion in the preface. It would be a misfortune if no one were found able and willing to carry on a work of such value and importance both to the hospital system and to the public at large.

*Whitaker's Almanack*⁴ this year completes its first half-century. It has become so familiar a part of the furniture of the worker's desk that it is hardly necessary to praise it. It is the most remarkable annual cyclopaedia anywhere published. This edition appears to be made up to the end of October, 1917, and the diary of the war is continued to that date. There is a special section on the new Empire honours, but the lists have, of course, been rendered incomplete by the recent New Year's awards. Attention is called in the preface to the steady growth of Government departments, and their constitution and principal officers are, as a rule, duly noted; but here again, in many instances, changes have been made very recently. The navy and army lists have been omitted entirely, as nothing adequate relating to either service could be presented, and we agree that the excision was inevitable. The book remains the most convenient current work of reference.

On November 3rd, 1917, we published (p. 594) a note of the story Dr. W. W. KEEN had then recently published of the case of the late President Cleveland. The matter has now been issued in a small volume entitled, *The Surgical Operations on President Cleveland in 1893*.⁵ Dr. Keen has written a foreword which makes one or two points plain.

MEDICAL AND SURGICAL APPLIANCES.

Photographic Papers for X-Ray Work.

MESSRS. ILLINGWORTH AND CO., Park Royal, Willesden Junction, London, N.W.10, have sent us samples of special papers they have placed on the market for printing from x-ray negatives. They are made in both bromide and gaslight varieties, and, in addition to the standard grade for average negatives, there is a special grade for weak and thin negatives. They can be used with the W. O. x-ray plate developer in use in military hospitals, and the makers supply full information as to the best method of development. The papers have been tested for us, and have been found excellent in every way. The quality of the paper base is good, and the emulsion gives good detail and vigorous prints with good contrasts; the papers are therefore very suitable for x-ray pictures.

British Medical Journal.

SATURDAY, JANUARY 19TH, 1918.

THE WISE USE OF MEDICAL MAN POWER.

THE speech of the Minister for National Service in the House of Commons on Monday brought before the country the position as to man power with a frankness which was the truest wisdom. He insisted on the paramount importance of the navy, and mentioned that the personnel of the navy, which stood at 150,000 in August, 1914, had risen in October, 1917, to 400,000. He called on us to return to the faith of our forefathers and to recognize that on the sea and by the sea we lived. Though we are called upon to play a larger part in the field of battle until America comes in, and that means more men for the army, it does not mean men regardless of the vital industries which support the armies, and not men nor munitions of war regardless of the navy on which all else depends, nor men regardless of food on which the health and endurance of the people depends. The British army to-day has, he said, on its rolls over four million men, and altogether the British nations have provided for the armed forces of the Crown not less than 7,500,000. Of these, 4,530,000, or 60.4 per cent., have been contributed by England; 620,000, or 8.3 per cent., by Scotland; 280,000, or 3.7 per cent., by Wales; 170,000, or 2.3 per cent., by Ireland; and 900,000, or 12 per cent., by the Dominions and the Colonies. The remaining million men, composed of native fighting troops, labour corps, carriers, and so on, represent the splendid contribution made by India, Africa, and other parts of the empire.

He went on to show that the demand now existing for more men for the army could be met from two sources—the reserve now in the armies at home and abroad and the men still in civil life. The composition of the armies at home is being readjusted so as to enable the greatest possible proportion of the demands of the armies overseas to be met within the army itself, but, when all was done, it was necessary to proceed immediately to raise in this country 420,000 to 450,000 men from among those now in civil life. On the other hand, measures were to be taken to return simultaneously a large number of men from the forces to civil life, and in particular to avoid calling upon men who have been seriously wounded to fight again. The ideal of the Ministry was a system of recruitment based on occupation, conditioned by age, and it might be by marital state. The intention was to reinforce the army with the youngest men that could be got, but not to lower the age (18). Young men would be taken out of essential industries and their places supplied by men of those trades who had fought and had been wounded, if male substitutes were necessary at all.

The Military Service (Review of Exceptions) Act, 1917, would be administered with great care and consideration. Until recently, he pointed out, recruiting had been regarded as purely the duty of the military authorities: it was now a civilian duty, and Great Britain was for the purpose of recruiting divided into ten regions, each under an officer responsible for the due administration of recruiting within his region. Sir Auckland Geddes was able to assert that the

machine was running smoothly and well, and though he did not say so, we believe that this is largely due to the successful working of the Medical Department of the Ministry. The first duty of that department was to take over the arrangements for the medical examination of recruits and to establish recruiting boards on a civilian basis. In planning out this work the policy of the Medical Department of the Ministry has been to make use of the central and peripheral machinery already existing in the central Professional Committees and the Local Medical War Committees throughout the country. The loyal co-operation of these bodies with the Ministry is fully recognized. The Local Medical War Committees were asked to suggest the names of practitioners in each area who would be able to give part-time services upon the National Service Medical Boards, the idea being to spread the work as far as possible over a number of practitioners, each giving part-time services, rather than to employ whole-time medical officers. It was recognized that this would lead to greater economy in the use of medical man power. The actual appointments to the panels, out of which, from day to day, the boards are constituted, remain in the hands of the Ministry, along with discretionary powers as to altering or adding to the lists of names suggested by local committees: in one or two instances the boards are still conducted under the old whole-time system, but this is merely a matter of temporary convenience, and in nearly every area they are now working on the new basis and working satisfactorily. Each board is under the chairmanship of a Deputy Commissioner of Medical Services, who is a whole-time officer appointed directly by the Ministry. The new system of gradings provides standards of comparison of physical fitness for which a good claim to scientific accuracy can be established.

As a part of its general duty to estimate and organize the man power of the country the Ministry has become responsible for the supply of medical men to the military services and for their selection, with due regard to the needs of the civil population, among whom, it must never be forgotten, workers in munition and other essential trades are included. It is hoped that with the improvements in the distribution of medical officers in the army, both abroad and at home, with the practice of strict economy of medical men at all fronts, and with a continuation of the generous assistance given by America, it may prove possible to avoid further calls upon the civil profession to supply more medical officers for the army; but we believe that with the great increase in the personnel of the navy mentioned by Sir Auckland Geddes the demands of the medical service of that arm are becoming more insistent.

The Ministry of National Service has recently been approached by the Ministry of Pensions with a view to providing the personnel and, in general, organizing the establishment of boards at discharge centres to examine the soldier upon discharge and estimate his pension, and of Pensions Boards for the periodical re-examination of pensioners. Arrangements are in course of being completed by which the Ministry will, in appointing these new boards, act upon the same lines as before—that is to say, it will obtain suggestions as to suitable practitioners from the Local Medical War Committees, though reserving to itself powers in regard to the actual appointment.

The establishment of numerous boards in this way has necessitated a wide survey of medical man power in the country, in order that the different forms of Government work may be so distributed as to secure, in the first place, the right man for each form of work,

and to ensure, in the second place, that each medical practitioner is as far as possible doing his proper share of it. It has thus become increasingly necessary for the Ministry to undertake the general survey of the medical man power of the country, and it is in this connexion that medical men of military age have recently been asked to submit themselves for physical examination. Very busy practitioners may not find it easy to give the time for this examination, but it is hoped that when they realize that the request is not an idle one they will cheerfully respond.

The Deputy Commissioners in the different areas will work in close co-operation with the Local Medical War Committees and with other medical organizations, and will act as the outposts of the Ministry in the country, being responsible for supplying to it all information as to the employment of medical men in their areas.

The Ministry of National Service has been called into existence to meet an emergency, but as is here indicated its scope is already wide, and its work will not come to an end with the war, however that ends. It may have, and we believe will have, a great influence on the future of the medical profession, and we rejoice to think that it has not at once set to work to create a large new corps of medical officials, but is seeking to enlist the help of doctors actively engaged in general practice.

THE USE OF POTATOES IN BREAD-MAKING.

At recent meetings of the Académie de Médecine¹ MM. Maurel and Gautier have discussed a question of great practical importance—namely, the utilization of potatoes in bread-making. The discussion was initiated by M. Maurel, who communicated the results of his observations upon bread made from wheat flour (milled to 85 per cent.) and potato pulp, the percentage of the latter increasing from 20 to 50 per cent. The nutritive values of the mixtures were found to be as follows, per 100 grams: In 20 per cent. potato bread, calories 308; in 30 per cent., 283; in 40 per cent., 259; in 50 per cent., 234. Protein, in 20 per cent. potato bread, 8.51; in 30 per cent., 7.68; in 40 per cent., 6.84; in 50 per cent., 5.97. All these breads were found to be well risen and elastic on removal from the oven; they kept fresh a considerable time, only losing 2 per cent. of weight in forty-eight hours; and, even with 50 per cent. potato pulp, retained a satisfactory odour of wheaten bread. The bread absorbed liquids, and was consequently insalivated more easily than that prepared without admixture. Maurel suggested that the decreased nutritive value with increasing admixture of potatoes could be avoided by the introduction of bean flour, his suggestion being to use 60 per cent. wheat, 30 per cent. potato, and 10 per cent. bean flour. In his opinion the use of potatoes in baking was impracticable for small private bakers, but both possible and desirable in State, communal, and army bakeries, as well as in families that make their own bread; he gave statistics showing that in this way important economies in wheat consumption might be effected.

In his criticism of this communication M. Gautier referred to the potato bread prepared by the orders of the Minister of Revictualling and recommended in a circular to the prefects on August 7th, 1917. This bread contained 20 per cent. of potato flour and possessed an energy value of 253.6 calories per 100 grams (6.90 grams protein). Gautier did not

deny that the ministerial bread possessed the merits claimed on its behalf, but he dissented from the view that such a bread could be prepared by private bakers, and emphasized the difficulties in this direction to which Maurel had alluded. Gautier believed that it would be better to reduce the bread ration rather than further to dilute the official loaf with substitutes for wheat, and to encourage the public to use potatoes and other vegetables cooked in the normal way. M. Gautier's criticism does not take account of an important advantage associated with the use of potatoes in bread rather than in their natural state. We have already directed attention to the difficult problem of internal transport, and it might be much easier to organize deliveries of supplies to large bakers, than to retail greengrocers when we are concerned with the very large quantities in question. There is also the difficulty of giving variety to the cooking of potatoes when fats are scarce.

The Ministry of Food has taken up the subject and we have received a sample loaf containing 10 per cent. of potato flour. Particulars have not been supplied of its analysis, but, so far as appearance and palatability are concerned, we can testify that M. Maurel's claims are just. The bread seemed to us of better flavour than that baked from ordinary G.R. flour, and a portion preserved for twenty-four hours (that is, eaten at least forty-eight hours after baking) seemed less stale than our customary war bread. If other bakers are able to reach the Ministry's standard, the potato bread should be in great demand, and, from the physiological point of view, as we have more than once remarked, its use is very desirable on account of the superior biological value of potato protein in comparison with that of wheat. The public should be urged to try the new bread at once, and we understand that the use of a certain percentage of potatoes in bread-making is about to be made compulsory.

SIR ALFRED KEOGH.

SIR ALFRED KEOGH retires from the office of D.G., A.M.S., leaving behind him the reputation of one of the greatest organizers and administrators the army has produced. It was not an accidental coincidence that he and Sir William Robertson received the G.C.B. on the same day about a year ago. When he took up the office for the second time, in October, 1914, he knew that he had undertaken a task beset with difficulties. He succeeded in carrying day after day a burden of responsibility and labour which only a man of his energy, enthusiasm, and mental calibre could carry. He had to meet at once the medical needs—which then seemed immense—of the new armies of men who voluntarily responded to Kitchener's appeal. The response came in a manner redounding to the everlasting honour of the British medical profession. The response must have heartened Sir Alfred Keogh in those difficult early days after Antwerp and the first battle of Ypres. It would have been made whoever had been in his place, but it was made more readily and with more confidence because he was there. Men at such moments do not stop to analyse the springs of their conduct, but there can be little doubt that the spontaneity of the response was in part due to the feeling that Sir Alfred Keogh was one of us; that through his long years of military administration he had never forgotten that he was a doctor first and a soldier afterwards. He has said this or something like it very often, and his record in the service would stand as evidence had he never said it. The work of the enlarged Army Medical Service, of which he has had the central direction, has been greatly successful in the prevention of disease, in the treatment of the wounded and sick, and in their transport and hospitalization. The first urgent problem

¹ *Bulletins de l'Académie de Médecine*, Nos. 43 and 44, sittings of November 6th and 13th, 1917.

of the war on the Western front was raised by the frequency of wound infections of extraordinary severity and of types which, if not new, were unknown except by name to modern surgeons. Then appeared at once the wisdom of the appointment of consulting surgeons, physicians, and pathologists, and the establishment of clinical and research laboratories under the direction of skilled men of the younger school. In all this Sir Alfred Keogh has shown a quality which distinguishes a great from a good administrator, a quality which he shares with his distinguished colleague in France, Sir Arthur Sloggett, of encouraging men of capacity, in the words of Harvey, "ever to search out and study the secrets of nature" at the bedside or in the laboratory. In the course of his multifarious work of the last three and a half years Sir Alfred Keogh has had to touch the fates of ten thousand medical men of all ages, dispositions, and clinical acquirements. That the Army Medical Service has during these times always succeeded in using its civilian recruits to the best purpose would be to claim too much. It is not in mortals to avoid mistakes, but we are quite sure that throughout it all the retiring Director-General has been inspired by a real appreciation of the importance of scientific methods, by a genuine love of his profession, and a whole-hearted desire to do the best possible for the armies and for the sick and wounded. In choosing Sir Alfred Keogh's successor, the precedent recently created in other branches of the army, of looking to the younger men, has been followed. Colonel Goodwin, who entered the R.A.M.C. in 1893, is not yet 47. He served with distinction in frontier expeditions in India and has won golden opinions in this war where he served in France from the earliest stage, as more recently in America, to which country he proceeded as a member of Mr. Balfour's mission last spring. He has a difficult succession; we wish him every success in the high office to which he is called.

THE STAFFS OF THE INSURANCE COMMISSIONS.

A REPORT on the administration of National Health Insurance during the years 1914-17 has been presented to Parliament and published.¹ The last report was that dated June, 1914, and dealt with the year then terminated. In 1915 it was resolved to suspend the publication of an annual report, owing to the conditions arising out of the war, and in particular to the serious depletion of the staffs of the Joint Commission and the several commissions. It has, however, now been considered advisable to publish a report covering the period from the outbreak of war to November, 1917, more especially as several matters of interest have to be recorded relating to the adaptation of the machinery of National Health Insurance to war conditions. Precedent is followed in the division of the report into parts describing the work of the Joint Committee and the several commissions; but, in view of the shortage of paper, and as many of the details of administration are the same in all the four countries, they are described fully in the part dealing with the English Commission, the reports of the work of the Scottish, Irish, and Welsh Commissions supplementing that description wherever the conditions in those countries depart from those prevailing in England. The male staff of the Joint Committee at the outbreak of the war was 39, including 11 men over military age; this has been greatly reduced, as 15 have been released for military service (of whom 3 have been killed) and 13 lent to other departments engaged on war work. The net result in the loss to staff has been 71.8 per cent. For similar reasons the male staff of the English Commission has lost 720 out of 1,106, or 65 per cent. This loss has been met mainly by the engagement of women, of whom

there are now nearly 1,600 in the employment of the Commission. Of the members of the staff on active service 63 have lost their lives, and in addition 2 have been missing since May, 1917, 1 is interned in Holland, and 2 are prisoners of war in Germany. One member of the staff, Sub-Lieutenant A. W. St.C. Tisdall, R.N.V.R. (killed in action), received the Victoria Cross. Prior to the war the Scottish Commission had 261 men in its employment, of whom 213 were of military age; at the present time the corresponding figures are 72 and 44. Of the staff on active service 23 have died, 1 is reported missing, and 1 is a prisoner of war. The Welsh Commission has been able to release 117 out of the 167 male officers it had at the outbreak of war; 11 have been killed, and 1 is missing. The staff of the Irish Commission included 213 male officers at the outbreak of war, of whom 172 were of military age; 45 members, constituting 21 per cent. of the total male staff and over 26 per cent. of members of military age, have voluntarily joined the forces; 9 have lost their lives, and 2 are reported missing.

TRENCH FEVER AND "P.U.O."

WE would direct the attention of our readers—civilian as well as military—to the preliminary report printed in another column, of a committee nominated by Sir Arthur Sloggett to investigate the cases of obscure pyrexias occurring in the army in France, which are variously known nowadays as "trench fever," or "P.U.O."—that is, "pyrexia of unknown origin," as commonly transliterated, but really signifying "pyrexia of uncertain origin." Indeterminate fevers have been very prevalent since the first winter of the war; and although never directly fatal they are the cause of much invaliding and sometimes destroy a man's fitness for military service. The committee and the medical officers associated with them had the advantage of studying a considerable number of unselected patients who were collected at an early stage of their sickness in a hospital set apart for this purpose. The present communication confines itself to an attempt at clinical classification based on an analysis of the notes taken by the medical officers in charge of the cases. Considerations of etiology, pathology, prevention, and cure are reserved for a later report. From the general mass of clinical observations three fairly distinct types of pyrexia emerge: the relapsing, styled for convenience "trench fever"; the single short initial bout of fever, recalling influenza; and the prolonged initial fever, resembling enteric. The first type is divided into regular relapsing and irregular relapsing subtypes. Apart from the course of the pyrexia, however, the four groups are indistinguishable by any clinical test. Headache is invariable, and pains in the limbs and back are common to all, as is a strong tendency to persistent tachycardia when the temperature is subsiding. The report brings out clearly the causal relationship between P.U.O. and many cases of disordered action of the heart. The absence of intestinal or renal symptoms is noteworthy throughout the series. Enlargement of the spleen was fairly frequent—a condition not observed by those who described the earlier cases. It is interesting to find splenic enlargement now definitely associated with P.U.O., because we believe that in the first year or two of the war this sign was generally held to indicate an enteric group infection. The first report of the committee marks a step forward in the precise clinical investigation of a very obscure group of diseases, which, as we have said, are not without interest for civil practitioners in this country. There can hardly be a doubt that trench fever, at least, is infectious. It was first recognized in the trenches, but it began to occur among orderlies in medical units further back where the sick were nursed, and eventually at schools of instruction on the lines of communication to which men were sent from the trenches. McNee, Renshaw, and Brunt, in a paper published in our columns nearly a year ago,

¹ H.M. Stationery Office. To be obtained through any bookseller. (Cd. 8890.) Price 1s. 6d. net.

showed that it could be transmitted from one person to another by whole blood. There is strong evidence that the disease was imported into the armies at or near Salonica by troops coming from France, and it is therefore not impossible that it may be imported into this country or may have already been transmitted to persons brought into close contact with soldiers returned from France. The Trench Fever Committee for this country, which sits at the Royal Army Medical College, Grosvenor Road, London, S.W.1, under the chairmanship of Surgeon-General Sir David Bruce, K.C.B., has, indeed, asked that reports of suspicious cases may be sent to it. Sir Wilmot Herringham and his colleagues are very cautious in drawing any conclusions in their preliminary report, but the known facts may, perhaps, justify some speculation as to whether among the cases once common in marshy districts in England, and then commonly called "marsh fever," there may not have been some of the varieties of feverish disorder described in their report. No doubt the majority of the cases in the Fens and in the low marshlands of Kent were malaria, but it seems possible that some may have been instances of the newly recognized disorders, trench fever and its congeners.

THE MEAT POSITION.

MR. CLYNES stated in the House of Commons on January 16th that 10,000 returns from slaughterhouses in Great Britain indicated that in December, 1917, the number of cattle slaughtered for beef was 9.5 per cent. greater than the number slaughtered in December, 1916. The number of live stock in the country, he said, is estimated to be lower than a year ago, so that supplies of home-fed beef for the next four months, equal to those of the same period last year, could only be forthcoming at the expense of a further depletion of our live stock. It is generally believed that during last year the habit of eating much meat has greatly increased among the industrial classes; this is an intensification of a tendency which, for good or evil, has been growing during the last quarter of a century at least. In a well-known "purple passage" Macaulay predicted that "in the twentieth century . . . labouring men may be as little used to dine without meat as they now are to eat rye bread."¹ This expectation has been more than fulfilled, and some general statistics will not be without interest. According to Gregory King, who estimated the population in 1696 as 5,500,000, about 2,700,000 ate meat daily; of the rest, 1,540,000 ate meat at least twice a week, while 240,000 were either sick persons or infants under 13 months old. There remained 1,020,000 persons "who receive alms, and consequently eat not flesh above once a week."² Adam Smith observed that "in almost every part of Great Britain a lb. of the best butcher's meat is, in the present times, generally worth more than 2 lb. of the best white bread; and in plentiful years it is sometimes worth three or four lb."³ We recently gave statistics of the consumption of meat by the English working classes shortly before the war. The figures were as follows: Industrial families in urban districts consumed from 1 lb. 9 oz. to 2 lb. 6 oz. per "man" and week, the lesser amount referring to families with weekly earnings of less than 25s., the greater to those with wages over 40s. No satisfactorily comparable data are available for European families, but we deduce from Slosse and Waxweiler's statistics⁴ that even in Brussels and among skilled operatives the weekly consumption of all forms of flesh (including bacon, etc.) was not much more than 3 lb. In Germany, since the war, the most favourable data, those of Loewy,⁵ show a weekly consumption of 0.77 lb. to 1.4 lb., the latter figure concerning

families with a monthly income of more than 500 marks; the more recent evidence of Berg⁶ only reaches three-quarters of a pound weekly with labourers on heavy or very heavy work. In the face of the experience of our ancestors and the long deferred collapse of our enemies, it does not seem necessary to labour the point that a restricted meat diet, although, like the discontinuance of any pleasant habit, a hardship, is far from being a calamity. We do not, indeed, suppose that the meat shortage will continue to be so acute as it is at present, but we see no reason whatever to expect that supplies will again become abundant during the war or until long after its termination. This must necessarily follow from a consideration of the price of fodder, the demand on shipping, and the obvious economy of not interposing a non-human "profiteer" between the source of biotic energy and the human consumer. It is to be remembered in this connexion that 64 lb. of dry fodder are consumed in producing 1 lb. of dry human food in the form of beef.⁷ The position, then, has to be faced, and we conceive the course of action incumbent upon the educated and professional classes to be clear. They must, both by precept and example, urge upon the majority of their countrymen the desirability of ceasing to regard meat as a staple article of diet and the need of looking upon it as a mere relish or appetizer. We should like to see not one only but several meatless days introduced into all the clubs and restaurants, and no one should eat meat at home more than once a day. We have time and again urged the psychological importance of example; in this particular matter example is of really supreme value.

THE AIR MEDICAL SERVICE.

IN moving the second reading of the Air Force Bill last November, Major Baird, then Parliamentary Under Secretary to the Air Board and now to the new Air Council, said that one of the most important needs was for a specialized Air Medical Service, and he gave more than one cogent reason why a body of men must be obtained whose sole duty would be to concentrate on the new branch of medical science, upon which depend both the welfare of our flying men and the efficiency of the Air Service. To a mind trained in science the proposition is self-evident as soon as it is made. The inference followed that the air authorities had grasped the position in good time, and intended to set up an Air Medical Service to minister to the special and peculiar needs of the new Air Force which is now in its birth throes. This assumption underlay all that we wrote on the subject a fortnight ago, and there would be no need to go over any part of the ground again were it not for a rumour now current that the Air Council has unaccountably weakened in its resolve. Without entering into details, the case against such a reversal of sound policy can be stated in three sentences. The Air Force is to be a separate force distinct from the army and navy, with its own Secretary of State and its own Council. The presumption therefore is that it should be complete in all the branches represented in the other fighting services—that is to say, it should have its own medical service. Hence the onus of proof rests on those who oppose, not on those who advocate, the setting up of an Air Medical Service. We would urge, with all the emphasis at our command, that the Air Force, by reason of its special functions, its immense possibilities of future development, and the peculiar risks to which its personnel is exposed, must from the outset contain within it a specialized medical corps devoting the whole of its time and talents to the medical and physiological problems of flying, and the professional care of aviators and their retinue. It will not do for the Air Force to be served by medical officers doled out by the War Office and the Admiralty for uncertain periods of duty. We need only turn to Surgeon Graeme Anderson's paper on the medical aspects of aeroplane accidents (p. 73)

to realize that a practical interest in aviation is an indispensable quality in an air medical officer. Only within an Air Medical Service will it be possible to create a trained medical personnel graded according to the capacity of each individual for specialized duties, such as research work in hospital or laboratory, the medical charge of aerodromes and air hospitals, or the testing of physical fitness for aviation.

WITTENBERG PRISON CAMP.

At a meeting of the West London Medico-Chirurgical Society on January 13th, with Dr. A. J. Rice-Oxley, President, in the chair, one of the two gold medals of the society awarded last year was presented to Major Harold Edgar Priestley, C.M.G., R.A.M.C., in recognition of his devotion to duty during the typhus epidemic in Wittenberg Camp, Germany, from February to June, 1915. The President said that Major Priestley, in addition to his sufferings as a prisoner of war, had been twice torpedoed in the last ten months, and was now on sick leave from abroad. When he arrived at Wittenberg there were 12,000 prisoners of war and a number of civilians, but there were practically no drugs or medical appliances, and no proper sanitary arrangements. When typhus fever broke out, the German principal medical officer, Dr. Aschenbach, played the coward and fled the camp, and his colleagues did the same. Major Priestley thereupon devoted himself to the sick and dying until he fell ill himself. In returning thanks, Major Priestley spoke of the callousness and brutality of the German guards and the sufferings of his fellow prisoners, who, in spite of cruelty, hardship, and disease, never lost their courage or discipline. He paid a warm tribute to the work of his colleagues at Wittenberg: of the five medical officers two only have survived. In accepting the medal, Major Priestley said he regarded himself as holding it in trust for all those splendid men.

MEDICAL STUDENTS IN THE RANKS.

At the present time the withdrawal of medical students from combatant service in order to resume their studies is governed by Army Council Instruction 1751, the provisions of which were summarized in the JOURNAL of December 8th, 1917. Under this instruction students who at the time of their enlistment were engaged in medical studies and had completed their second year may, if they so desire, be released for the purpose of continuing their studies with a view to qualification. Students who do not pass the professional examination in anatomy and physiology within six months of resuming study will be recalled to the colours, and a student transferred to the Reserve who does not resume his studies and enrol in an officers' training corps will be recalled. The usual official steps have been taken to bring the instruction to the notice of all students serving with the colours, whether at home or abroad; but it is evident that in front-line formations, during periods of stress, information of this sort published in battalion orders may never reach those for whom it is intended. Here it may be pointed out that the official object in releasing medical students from the ranks is not to remedy individual cases of hardship, however desirable that may be, but to maintain the number of students in training at a level sufficient to produce an adequate supply of new medical practitioners for national needs. To effect this purpose more adequately, we understand that Army Council Instruction 1751 will shortly be amended, and that the Ministry of National Service will take steps to ensure that so far as possible all those concerned are made aware of the revised regulations.

SHELL-SHOCK PATIENTS IN AIR RAIDS.

EARLY in November a question was asked in the House of Commons with regard to shell-shock patients at the 4th London General Hospital, and other similar cases at Golder's Green, the suggestion being that the condition of these men is aggravated by air raids and that they ought

to be removed to a quieter neighbourhood. In a non-committal reply Mr. Maepheron said that it might be possible, in connexion with changes then being made, to discontinue the neurological centre in London as a treatment centre; he added that the inquiry as to Golder's Green should be addressed to the Minister of Pensions. In a letter printed in the JOURNAL of November 24th Dr. Thomas Luusden maintained that however convenient it may be for the authorities, it is bad treatment to congregate nerve-shattered men in hospitals unless the severity of their symptoms renders this unavoidable, and that it is unpardonable to keep even the serious cases in a town like London, where air raids are frequent. The description which he quoted of the effect of an air raid on nerve-shattered men was very painful to read, and we are assured by several informants that that account in no way exaggerated the state of things on such occasions. There can be little doubt that shell-shock patients are extremely liable to relapse under the mental stress of an air raid, and when cases of varying degrees of severity are grouped together at such a time the good effects of months of treatment may be undone in the course of a few minutes. We regret to have to add that so far as we can ascertain nothing has yet been done towards the early removal to the country of men suffering from war neuroses. The change would be in the interests of the patients, of economy of medical manpower, and therefore eventually of sound administration.

Medical Notes in Parliament.

Reassembling of Parliament.—When the House of Commons reassembled on January 14th, the Minister of National Service moved the first reading of the Man Power Bill in a very detailed speech. In the course of it he said that he wished he had the opportunity then to describe the reforms which had been introduced in the system under which men are medically examined. The old system had been replaced by a new one which, though it still showed a few raw edges, was a vast improvement on the old. He wished, too, that he could stop to tell of all the work that had been done to co-ordinate the demands of Government departments for medical men, and to ensure an adequate supply of medical practitioners to meet the nation's needs in 1920, 1921, and the years following. The efficient working of the recruiting and medical machines rested finally upon a complete and accurate system of registration. He welcomed, therefore, the measure Mr. Hayes Fisher had introduced to complete that work of registration.

Education Bill.—The Education Bill was introduced by the Minister for Education, on January 14th, under the ten minute rule. The bill, he said, was substantially the same as its predecessor, and attention to physical welfare remained a special and distinctive note, but certain of the administrative clauses had been omitted or amended. The clause with regard to medical inspection of schools and educational institutions reappears unaltered,

Medical Attendance at Military Hospitals.—On January 12th Sir R. Cooper asked a question which suggested that the recent replacement of British medical practitioners in military hospitals by American practitioners had broken down, and that British practitioners had been requested to return temporarily to work in the military hospitals. Mr. Macpherson replied that the facilities given to the American Government to enable its officers to obtain experience of war injuries had not broken down. The number of practitioners employed in military hospitals varied with the number of patients in them.

Treatment of Neurasthenics.—In reply to a question by Mr. King, the Parliamentary Secretary to the Ministry of Pensions said that there was no power to keep men discharged from the army under control, but institutions were being provided in which the severer cases of neurasthenia might be suitably treated. Two such institutions had been opened, and others would be ready for occupation shortly. The Ministry was advised, however, that the milder cases of neurasthenia should not be retained in institutions, and that it would not be to their advantage to be placed under the care of lunacy experts. In reply to a further question, he said that one of the new institutions was in the raid area of London, but none of the others now being got ready were in that area. When provision had been obtained outside, the advisability of moving the present institution would be considered.

THE WAR.

PRELIMINARY REPORT OF THE COMMITTEE UPON TRENCH FEVER AND PYREXIA OF UNKNOWN ORIGIN.

DURING the winter 1914-1915 many cases were admitted to hospital for "myalgia," "influenza," "neuritis," and even "rheumatic fever," which had as common symptoms pyrexia and local pains. In April, 1915, attention was drawn to a new kind of fever which was marked by relapses. It was described by Graham,¹ by Hunt and Rankin,² and by McNee, Brunt, and Renshaw;³ Hurst⁴ later described it at Salonica. Little has been added to their accounts. The name "trench fever" was given to it, since it arose in the front area. It was not found to originate on the lines of communication until the establishment of schools of instruction, to which men came from the front area, created foci of infection. It is to this form that attention has hitherto chiefly been directed. McNee found that he could convey the infection by injecting the whole blood or the red cells, but not by injecting the serum alone. But beyond this little has been learnt of its pathology. Pappenheimer⁵ described certain forms seen in the blood, and obtained by culture from the blood and tissues, but these were found to occur in other conditions also. Patterson,⁶ and later Nankivell and Sundell,⁷ described spirochaetes in the urine of these cases, but similar spirochaetes were found in the urethra of healthy men.

Dimond⁸ described a body which he called a haemogregarine. and the same body was found by Patterson, Perry, and Urwick, but it was proved to be a flagellate growing in the distilled water which had been used in preparing the blood films. No organism has yet been discovered which can be connected with this form of fever.

But it was always known that along with this relapsing form many cases occurred in which the temperature ran a very different course. These cases were mentioned by Hunt and Rankin, but have never been carefully observed or described.

These various forms of fever of unknown origin have been very prevalent; for every case of enteric there have been at least twenty of these indeterminate and innominate fevers. And though they never cause death, yet they often lead to a very long period of incapacity and sometimes to discharge from the service for ill health. They are therefore of great importance to the army. Accordingly the D.G.M.S. of the army in France nominated a committee, consisting of Lieut.-Colonel W. O. O. Beveridge and Colonels Sir John Rose Bradford, Sir Wilfrid Herringham, and Sir William Leishman, to examine and report upon them. No. — Stationary Hospital was selected for the reception of the patients, and, by arrangement with the D.M.S. of the army, and the D.D.M.S. of the corps in whose area the hospital was situated, the cases were sent in direct from the field ambulances as soon as they arrived. In this way a large number of unselected cases were obtained at an early date of their illness which had this common feature alone, that they were at their onset of unknown origin. They formed, in fact, a sample of P.U.O. in bulk as nearly representative as it could be made.

The cases were under the care of Lieut.-Colonel B. B. Burke, officer commanding the hospital, Captain Horsley Drummond, officer in charge, medical division, and Captain Urwick, pathologist, and in charge of wards. In October the services of Captain Perkins were obtained as special pathologist for these cases. It is an advantage that as there is an isolation hospital attached to No. — Stationary Hospital, cases found to be the subject of enteric fever could be transferred, and a comparison made with cases that were not enteric.

The aims of the Committee were:

1. To determine whether these cases of unknown pyrexia include more than one class of fever, and, if so, to classify them.

2. To observe the symptoms distinctive of each class that might be established, and thereby to distinguish one class from another, and from all known fevers.

3. To investigate the etiology and pathology of these fevers.

4. To discover the best means of prevention and cure.

It is upon the first two of these objects that the Committee desires to offer a preliminary report drawn from an analysis of the clinical notes taken by the medical officers. The report, however, is incomplete even under these headings, for it does not include a number of observations upon certain symptoms, and upon the condition of the blood, which are still in progress, nor does it deal with the diagnosis from enteric and influenza. In the present series, the object of which was to obtain a general picture of the cases diagnosed as P.U.O., a few cases of enteric are known to be included. They are, however, so few that the general conclusions are not thereby invalidated. This will be considered at length in the next report.

CLASSIFICATION.

After consideration of other principles, the only classification that seemed at all satisfactory was that based on the character of the temperature chart. These fall into three classes—

A. The relapsing class (trench fever).

B. A class with a single short initial bout of fever and no relapse.

C. A class with prolonged initial fever.

It gives perhaps a more vivid picture if it be added that Class B recalls influenza, and Class C an enteric fever.

The total number of cases is 170 in which there is only one officer. Of these the relapsing class A includes 91 cases, B includes 27 cases, and C 52 cases.

They were all in hospital during July, August, and September, 1917. It may be that the autumn and winter cases will show modification of the symptoms now reported.

CLASS A.—TRENCH FEVER.

91 Cases.

The cases in this class are divided into—

1. Regular relapsing, with definite normal intervals = 56 cases.

2. Irregular relapsing, in which the intervals between the relapses are not so definite, or if the intervals are definite the temperature remains above the normal = 35 cases.

It seems indubitable that these cases belong to the same class, but it is important to notice that there is both a true intermittent and a remittent variety. In the following analysis of symptoms the whole class is taken as one. (See Charts 1, 2, 3, illustrating A 1; Charts 4, 5, illustrating A 2.)

Previous History.—In 9 cases a previous attack of P.U.O. was known or probable. In 2 cases a previous attack of malaria was known or probable.

Immediate Antecedents.—The cases occurred in all situations—trenches, dug-outs, canvas, huts, and billets. Lice were present within twenty-one days in all but 18 cases. Mosquitos had definitely bitten 22 patients.

Prodromal Symptoms.—In very few cases. Coryza in 4, diarrhoea in 3, constipation in 4, malaise in one.

Onset.—Sudden in all but 9 cases. Usually the patient could tell what he was doing at the time. There is nothing else peculiar in these 9 cases.

Initial Symptoms.—*Headache* was invariable. It was nearly always frontal, and often referred to the back of the eyes. There was often conjunctivitis (pink eye). *Shivering* occurred in 24 cases, *dizziness* or *giddiness* in 33, several complained of weakness or faintness, and four actually fell down. There were *pains* in the back or lower limbs in most cases. In a few there was no pain other than headache at the onset, and in six this was the only pain throughout. *Vomiting* took place in 24 cases, and *nausea* in 4 others, *diarrhoea* in 4 cases, *sore throat* in 6.

On Admission.

The patients complain of headache and pains in the lower limbs, usually in the thighs and knees. They often look very toxic, and are flushed and sometimes drowsy. The tongue has a central streak of yellow or brown fur with red edges, the appetite is bad, the bowels constipated.

There is no distension of the abdomen. There is no abnormality in the heart or lungs. In 10 cases there was a trace of albumin, which disappeared in two or three days.

Course and Progress.

1. The *temperature* chart is marked by a series of 'bouts' of fever, in which the temperature as a rule rises rapidly, and falls rather more slowly. In some cases the rise is gradual. Taking the first bout as an example, the temperature on the first day was known in 18 cases. Of these, in 10 cases

CHART 1.

it was highest on the first day. In 3 cases it was as high on the second day as on the first day. In 5 cases it was highest on the second day. The acme is usually between 102° and 103° F., but is sometimes higher. The temperature is always falling by the third day.

The first bout lasted in 1 case one day, in 6 cases two days, in 18 cases three days, in 15 cases four days, and in 6 cases five days. In the great majority, 33 out of 46, it lasted three or four days.

The bouts vary greatly in number. Most patients have three or four bouts. One of this series, who seemed to be reinfected about the thirtieth day, had as many as seven.

If the acme of each bout be noted, or, supposing there are two days on which the temperature is equally high, the first of the two be called the acme, it will be found that there is a considerable regularity in its occurrence. Thus in the regular group the following sequences are found. The numbers are the days on which the acme of each bout was registered:

Case 12: 1, 5, 10.

Case 40: 1, 6. Case 32: 1, 6, 11. Case 30: 1, 6, 11, 17, 24.

Case 13: 1, 6, 12, 17, 23. Case 43: 1, 6, 12, 18, 24.

Case 38: 1, 6, 13.

Case 31: 1, 7, 12, 18. Case 18: 1, 7, 14, 23.

Case 10: 1, 8. Case 17: 1, 8, 16, 23. Case 1: 1, 8, ? 17.

Case 11: 2, 8. Case 8: 2, 8, 14. Case 15: 2, 8, 16.

There is a tendency for the acme to postpone as the disease progresses. There is also a tendency for the highest point to become gradually lower with each bout, as in Chart 2.

As a rule, when the bouts cease the temperature remains normal, or under 99° F. But in some there follows a period of irregular fever, which may sometimes last several weeks (Chart 6).

2. The *pulse*, which is commonly about 100 during the first bout, falls to about 70 as the temperature sinks to normal, and rises again, though not to so great a height, during subsequent bouts. It is the rule that it varies with the temperature so long as the bouts continue to appear. But at a later stage there has been in many cases great disturbance of the circulation. The pulse has become frequent, the heart has dilated under observation (the apex once went as far as 2 in. beyond the nipple), and a faint systolic bruit has been heard. The apex usually retreats again, and the bruit ceases to be heard if the patient is retained. These cardiac signs appear to be due to dilatation alone, and there has been no reason to believe

that endocarditis had been present. Since the plan was adopted of keeping almost every case in bed for twenty-one days tachycardia has been much less frequent. Yet it has appeared in several cases while the patient was still in bed, and, when it has appeared after the patient had got up, it has not been quickly relieved by putting him to bed again. There is no reason to suppose that the cases under observation were worse than the average, and it seems, therefore, probable that many cases of disordered action of the heart take their rise in trench fever. Chart 7 shows a remarkable degree of the condition.

In the whole 91 cases there were 24 in which severe tachycardia existed. Five of these patients complained of precordial pain, and in one the pain spread down to the left arm.

3. When trench fever was first described in 1915 the *spleen* was not found to be enlarged. In 1916 several cases of splenic enlargement were seen, and in the present series the spleen was definitely palpable below the ribs in 35 cases out of 91. One of the committee has been observing trench fever at the front from the beginning, and has no doubt that the proportion of cases which show this feature has increased.

The enlargement, or rather the extent of the organ which can be felt, is small. An inch or an inch and a half below the margin of the ribs is rarely exceeded. Four cases have shown greater enlargement than this, but of them one certainly and one probably were the subjects of old malaria. In these four the spleen was palpable the whole time the patient was in hospital. In 12 cases the spleen was palpable on admission, in 1 eleven hours, and in 1 seventeen hours from the onset.

It retreated behind the ribs before the twenty-fourth day in 21 out of the 35 cases in which it was palpable. But in 2 of these it reappeared later and in others it retreated and reappeared within the period of twenty-four days. It sometimes reappears during the relapses. It is probable from this that the spleen is often enlarged when it cannot be felt. It is sometimes tender, and to this are due the pain and tenderness in the left hypochondrium which were noticed by earlier observers, and were found in eleven patients of this series. This hypochondriac tenderness and the accompanying rigidity may occasionally prevent the spleen being felt.

4. Almost every patient complains of *pains* in various parts during the course of the disease. Apart from headache, which is universal and often very persistent, the most frequent site of pain is the lower limbs. All parts of these—thighs, knees, calves, shins, and ankles—are affected. The shin pains, which occurred in 44 cases out of 91, are described as in the bone itself. There is nothing outwardly to account for them. There is no thickening as

CHART 2.

in periostitis, and though the shins and other painful parts are sometimes tender, yet in many cases there is no tenderness, though the pain is severe enough to prevent sleep. Captains Drummond and Urwick have found tender areas, ill defined, in the skin of the legs, and in several cases hyperaesthetic zones corresponding to the distribution of one or two of the lower dorsal or lumbar roots. But they have never up to now found either subcutaneous nodules or anaesthetic patches, weakness or wasting of muscles, or tenderness of the nerve trunks, such as occur in true neuritis. The upper limbs are occasionally the site of pain. Backache is very common.

These pains vary from day to day in such a manner as to suggest malingering. Those, however, who have watched the cases are convinced that the complaints are

CHART 3.—This chart we owe to Lieut.-Colonel J. Clarke and Captain Parr. The case was seen by one of us in consultation, but is not of our series. It was typical. The patient felt quite well during the intervals, except for rather persistent headache. The remarkable character of the chart led to careful observation by Captain Parr and the sister in charge, who can vouch for its accuracy.

genuine. As examples of their fleeting character, two cases may be quoted:

Case 6.

- 1st day, headache and pain in loins and thighs.
- 2nd day, pain in loins, thighs, knees, and calves.
- 18th day, pain in knees.
- 21st day, pain in thighs and knees.
- 33rd day, pain in legs (not shins).
- 42nd day, pain in legs and back.
- 56th day, pain in calves and back.

CHART 4.

Case 31.

- 1st day, headache and pains in the abdomen, shins, and knees.
- 8th day, no pain.
- 12th day, pains in left side of chest (pulse normal).
- 15th day, no pain.
- 16th day, pain in left side of chest and shins.
- 19-26th day, no pain.
- 30th day, pain in shins.
- 34th day, pain round loins.
- 39th day, pain in back.

5. The *respiratory* system has been unaffected in this series of cases. The climate in this part of France is, however, extremely wet, and coryza and bronchitis are rife for a great part of the year. At such times patients with trench fever often have coryza and bronchitis. But they seem no part of the disease itself.

6. The *tongue* cleans and the appetite returns in a few days. Constipation is common.

7. There has been no *renal* affection in this series except in a few cases, the transient albuminuria mentioned above.

8. *Herpes* about the lips is not uncommon. In a considerable number of cases, in which there was no suspicion of enteric, small erythematous spots have been found, roundish in outline, level with the surface, and fading on pressure. One of the patients in whom these spots were seen had never been inoculated against enteric, but showed no rise in agglutinations, and gave no result to cultures of blood, urine, or faeces. It is rare to meet with a man who has not been inoculated, and such an example is conclusive.

Similar spots have been found in cases admitted for slight surgical ailments without pyrexia. These spots sometimes occur with relapses of the fever. A subsequent report will furnish further details on these spots.

To a further communication is also left the full account of the bacteriological examinations, and of certain other clinical symptoms.

Event.

Of the total number 32 were discharged to duty, of which 21 were in hospital over five weeks, and the remainder were evacuated to the base. Fourteen were evacuated rather early because of pressure on the hospital accommodation. Nineteen were evacuated for tachycardia, of whom 10 had dilatation of the heart. Four others had dilatation without tachycardia. Five had fever still continuing after thirty days or more of illness.

CLASS B.

In this class were placed (a) those cases in which there was only one short initial bout of fever, lasting under six days, and (b) those cases in which the illness was not observed or recorded during the first days and showed no definite relapses or high fever, but was diagnosed as P.U.O. The total number is 27.

It has sometimes been stated that there are cases in which the temperature never rises above 100° F. even at the first, but remains slightly febrile for many weeks, and that this class of cases is marked by unusually severe pain. Some have even coined the name "shin fever" for cases so described. A long low fever not infrequently occurs after the regular relapses of Class A, such as is

illustrated in Chart 6. It remained to be seen whether this ever occurs without an initial bout.

There are 9 cases out of the 27 in which no initial bout is known, but in four of these the patient was not seen till the third day, two were seen on the fourth day, one on the fifth (an officer who said his temperature had been 101° F.), and two later. So that in none could it be said that there had not been an initial rise. The remaining 18 cases all showed a definite initial fever.

There is therefore no evidence of a prolonged low fever without an initial bout.

On the other hand, while some cases have both a persistent fever and persistent pains, the two do not by any

CHART 5.

means always coincide. The case illustrated in Chart 6 had pains for at least seven weeks, but the preceding case in the series (A 1, 32), though showing a very similar chart, had but slight pain. In the present class, No. 16 shows a chart like Chart 6, but had no pain after the tenth day; while No. 22, though hardly ever above normal

after the second day, complained of pain for forty-nine days.

It is not necessary to record minutely the symptoms of this class. In the absence of prodromal symptoms, the

Reference will be made to this in a subsequent communication.

CLASS C.

This consists of 52 cases in which the initial fever is prolonged.

Previous History.—P.U.O. in 4 cases, malaria in 2 cases.

Immediate Antecedents.—The cases occurred in all situations, as in Class A. Lice within the last twenty days are denied by 7 cases, mosquito bites were found in 10 cases, and 13 other patients had noticed mosquitos.

Prodromal Symptoms.—Slight symptoms were present

in 8 cases before the onset of the fever.

Onset.—Sudden in all but 8 cases.

Initial Symptoms.—Headache was again invariable, and was usually frontal. Shivering and giddiness were as common, and the same weakness of the legs was observed. Pains in the back and lower limbs were again common. Vomiting took place in 14 cases during the first two or three days, and diarrhoea in four. There was sore throat in seven.

On Admission.

The symptoms were practically indistinguishable from those occurring in Class A.

Course and Progress.

The cardinal point of this class is that the illness begins with a prolonged fever. This varies greatly both in duration and character. In 19 cases it lasted

from six to nine days inclusive; in 20 cases it lasted from ten to fourteen days inclusive; and in 13 cases it was still more prolonged.

In some cases the chart has a curve that is roughly uniform, reaching its highest point about the middle (the hog-backed form, Chart 8). Some have their highest point at the beginning, and descend regularly (Chart 9). Some intermit for half a day or so, usually between the second and seventh days. And some recall the irregular relapses of Class A 2. As such cases should always be

CHART 6.—The temperature remained at the same level (99–100°) until the sixtieth day, when the patient was evacuated. There was no local condition to account for it.

sudden onset, the initial symptoms, and the character of the pains, it does not differ from Class A, but, as might be anticipated from the absence of relapse, there is a considerable proportion of cases in which the pains soon disappear.

Of 18 cases available the initial fever lasted in 2 cases only one day, in 4 cases two days, and in 4 cases possibly five days. Of 7 cases in which the first day's temperature was known, 6 showed the acme on the first day and 1 case on the second day. In 1 case the temperature reached 106° on the first day and was normal by the morning of the third.

There was a transient trace of albumin in the urine of 2 cases.

The spleen was palpable in 7 cases.

Tachycardia was severe in 13 cases, but in all save one it occurred after the patient had got up. These patients were ordered out of bed earlier than the relapsing class, as they seemed to have shaken off their fever. The increased proportion of tachycardia was probably a result of this. The single exception had a rapid pulse when admitted and was of the type that Lewis has particularly associated with tachycardia. One patient, on the other hand, had an unusually slow pulse. On five days it was registered between 50 and 60, and on four days it was counted at 48. He was in bed throughout, and though this temperature never rose above 99° after the fifth day, he suffered much with pain until the twenty-seventh day, when he was sent to the base.

Of the whole number, 16 were discharged to duty.

On the whole, these cases are probably to be regarded as pathologically akin to Class A, but without relapse. There seems no reason why, if one patient has four or more relapses, another only one, there may not be some who will have none. If it be granted that these patients are infected by some poison against which they produce an antibody, it may be possible for some to form this much more quickly than others.

This seems more reasonable than to link them with the prolonged initial fevers of Class C, next to be described. But there is a great difficulty in excluding influenza.

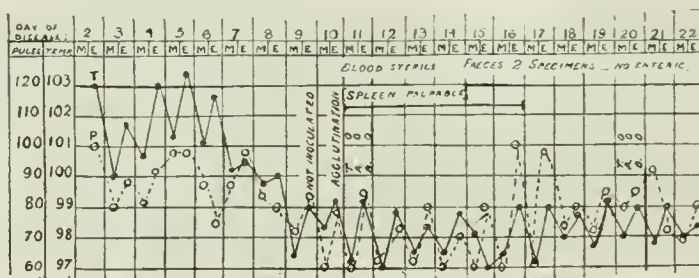

CHART 8.

CHART 7.—Evacuated in same condition on thirty-fifth day.

suspected of enteric, the cultural and agglutinative tests have been added to these charts.

This initial fever is often followed by a period of normal or subnormal temperature (13 cases), but in some there is no such normal period and the temperature remains irregular for a long time, and in a third group a normal

period is followed by bouts of irregular fever somewhat recalling Class A 2.

The pulse usually follows the temperature in this class as in Class A, but there were 13 cases in which

in all but one. In that case the urine did not clear till the twenty-fourth day, but at no time contained casts.

Of the whole 52 cases, 22 were discharged to duty. The remainder were evacuated.

CHART 9.

It remained at about 90, and in 2 it was very irregular throughout.

Tachycardia supervened in a severe form in 16 cases, and was the cause of most of the evacuations to the base. It usually began in the third week. Ten patients had not been out of bed when the condition set in. In several cases tachycardia lasted until the fiftieth day or longer, though the patients were kept in bed. Fourteen cases were sent to the base on this account. Dilatation of the heart was noticed in 14 cases.

The situation and character of the pains do not differ from those of Class A.

Splenic enlargement was found by palpation in 22 cases. In two patients, of which one had had malaria, it was palpable throughout the stay in hospital. Albuminuria to a very slight degree was found in 8 cases. It was transient

CONCLUSIONS.

1. There are three forms of fever of unknown origin (P.U.O.) now prevalent: the relapsing (trench fever), the single short initial bout, and the prolonged initial fever.

2. These three are indistinguishable from one another by any other symptoms than the course of the pyrexia.

3. All exhibit similar pains, all produce enlargement of the spleen, none show intestinal or renal symptoms of any importance, and all are apt to produce tachycardia.

THE MESOPOTAMIA DISPATCH.

APRIL-SEPTEMBER, 1917.

THE dispatch of Lieutenant-General Sir Stanley Maude, K.C.B., Commanding-in-Chief, Mesopotamian Expeditionary Force, dated October 15th, 1917, for the period April 1st to September 30th, was published in the *London Gazette* on January 10th.¹

During the five months ending April there had been continuous fighting, and during that month the enemy was driven back on divergent lines with the capture of 3,000 prisoners, 17 guns, and a considerable quantity of rolling stock and booty. All objectives had been secured, but the increasing heat rendered it necessary to redistribute the troops for the hot weather, and to make every possible provision to guard against the trying hot period approaching. The bulk of the troops were withdrawn into reserve and distributed in suitable camps along the river banks, where they could obtain the benefit of such breezes as blew, and where a liberal supply of water for drinking, bathing, and washing was obtainable. The heat was intense during the later part of June, in July, and at the beginning of August; consequently movements could not be undertaken by either side without grave risk of incurring substantial casualties from heat-stroke and heat exhaustion. The troops enjoyed a well-earned respite during the five months May to September. Sports, which are so essential to the well-being of the soldier, especially when temporarily inactive in a military sense, were freely indulged in, with beneficial results to the health and future fitness of the army for service in the field. Minor operations were, however, carried out during May, June, and July, and on July 8th Sinn El Zibban, on the Euphrates, was occupied. A further advance was interrupted by a blinding sand storm and a heat wave.

Active operations on the Euphrates were resumed on September 26th, and Ramadie was entered on September 29th, the Turkish commander and his staff being captured. During these operations the heat by day was considerable, and as they were conducted at some distance from the

river they were only rendered possible by the excellence of the arrangements for water supply. The captures included 3,454 prisoners, of whom 145 were officers, 13 guns, 12 machine guns, 2 armed launches, 2 barges, and large quantities of arms, ammunition, equipment, and stores. The dispatch contains the following reference to medical arrangements. Unfortunately before it could be received Sir Stanley Maude had himself succumbed to cholera.

The health of the troops during the summer months has been uniformly satisfactory, and many of the diseases from which we suffered in previous years—such as cholera, enteric fever, and scurvy—were either non-existent or negligible in their extent. This successful result was partly attributable to the untiring work of the officers employed in the bacteriological laboratories, without whose valuable assistance the difficulty of dealing with the epidemic diseases would have been considerably increased. But, although better conditions as regards accommodation and increased facilities for combating the heat resulted generally in a far lower sick-rate, an abnormal heat wave which swept over the area in July was responsible for a heavy casualty list. During this time the personnel of the medical services were severely taxed, but they resolutely and successfully responded to the calls made upon them. All ranks redoubled their exertions as the situation became more difficult, and the unremitting labours of the nursing sisters, many of whom suffered in health themselves, were worthy of the high record for devotion to duty which the nursing service has always maintained. The very practical assistance rendered by the British Red Cross Society and Order of St. John during this trying period was typical of the valuable services so consistently rendered by that organization.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died.

SURGEON E. Z. STIRRETT, R.C.N.

Surgeon Ernest Zavitz Stirrett, Royal Canadian Navy, whose death occurred in Toronto on June 22nd last, was born at Port Huron, Michigan, in 1889. He was educated at Toronto, and graduated from the university there in 1915. Soon after the outbreak of war he offered his services to the military authorities, and obtained a commission in the R.A.M.C. A few months later he was appointed ship's

¹ The preceding dispatch was noted in the *BRITISH MEDICAL JOURNAL*, July 14th, 1917, p. 60.

surgeon on one of the Allan Line steamers, and soon afterwards was transferred to duty on transports. He was subsequently appointed surgeon to the Patrol Fleet of the Royal Canadian Navy. His health, however, had been failing for some time, and at last he was obliged to give up his duties and return to his parents' home in Toronto, where he died a few weeks later at the age of 28 years.

ARMY.

Died on Service.

CAPTAIN R. W. CUNNINGHAM, A.A.M.C.

Captain Robert Wiseman Cunningham, Australian Army Medical Corps, died suddenly at Latrobe, Tasmania, on December 10th. He was the elder son of the late Surgeon-Major R. W. Cunningham, I.M.S., and was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1916.

CAPTAIN S. H. MORRIS, R.A.M.C.

Captain Sydney Herbert Morris, R.A.M.C., died in the London Hospital on January 11th, aged 42. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1899. After filling the posts of house-surgeon at the Seamen's Hospital, Greenwich, and at the Poplar Hospital, he went to South Africa, where he served as district surgeon, and later as acting principal medical officer to the British South African Administration, and was also a Justice of the Peace for North-East Rhodesia. On his return to England he went into practice at Frizington, in Cumberland, where he held the appointment of parochial medical officer and public vaccinator, certifying factory surgeon, and medical officer to the Post Office, till he took a temporary commission in the R.A.M.C.

CAPTAIN S. G. SCOTT, R.A.M.C.

Captain Samuel Godfrey Scott, R.A.M.C., died on January 6th in a casualty clearing station, on active service, of pneumonia, aged 42. He was the eldest son of the late Canon S. G. Scott, and was educated at St. Thomas's Hospital and at Oxford, where he graduated B.A. in 1897, and M.A., M.B., and B.Ch. in 1902. After serving as clinical assistant in the throat department at St. Thomas's, and as demonstrator of pathology in Leeds University, he returned to Oxford, where he held the post of demonstrator of histology to the university, till he took a temporary commission in the R.A.M.C. He was the author of numerous contributions to the medical and scientific journals.

CAPTAIN C. G. SHERLOCK, R.A.M.C.

Captain Charles Gregg Sherlock, who is reported as having died on service in Bagdad on November 14th, 1917, was the eldest son of Mr. Henry Gregg Sherlock, F.R.C.S.I., Professor of Dentistry at the Royal College of Surgeons, Ireland. He received his medical education at the School of Physic, Trinity College, Dublin, took the degree of M.D. in 1907, and joined the R.A.M.C. in August, 1908. He was in India when war broke out, and was sent to Mesopotamia in May, 1917. As a student Captain Sherlock played for the University Hockey Team. He was the first medical officer attached to the medical unit of the Dublin University O.T.C., and much of the success of this unit, which has sent so many men into the R.A.M.C., was, in its early days, due to his energy, popularity, and ability. Captain Sherlock was present at the successful T.C.D. dinner organized at Bagdad last September, which was honoured by the presence of the late General Mande. At the time of his death Captain Sherlock was 35 years of age.

Lost at Sea.

DR. H. L. BURGESS, W.A.M.S.

Dr. Harold Lynch Burgess, of the West African Medical Staff, was recently lost at sea. He was educated at the London Hospital, where he gained a prize for surgery in 1898, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1903, and the certificate of the London School of Tropical Medicine in 1905. After filling the posts of house-surgeon and casualty officer at the North-East London Hospital for Children he joined the West African Medical Staff. In 1913 he was seconded for special service at the Colonial Office, and had since served as medical secretary to the Advisory Medical and Sanitary Commission for Tropical Africa, and to the West Africa Yellow Fever Commission.

Wounded.

Captain J. G. Hill, R.A.M.C. (T.F.).

Lieutenant G. H. G. Davie, R.A.M.C. (temporary).

Lieutenant J. W. Lindsay, R.A.M.C. (temporary).

Prisoners of War.

Lieut.-Colonel H. C. D. Rankin, R.A.M.C.

Captain H. D. Clementi-Smith, R.A.M.C. (T.F.).

Captain C. F. Dillon-Kelly, R.A.M.C. (temporary).

Captain H. H. Fairfax, R.A.M.C. (temporary).

Captain E. F. L. Nash, R.A.M.C. (S.R.).

Captain F. B. Ryan, R.A.M.C. (temporary).

Lieutenant A. S. Gariwal, I.M.S.

Lieutenant T. F. Ryan, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Cromie, W. H., LL.B., Captain, late R.E., son of the late Dr. Robert Cromie, J.P., of Clough, co. Down, died on January 1st.

Postlethwaite, Christopher J., Lieutenant Suffolk Regiment, son of Dr. Postlethwaite of Breamton, Devon, died in a casualty clearing station of wounds on January 9th.

Phillips, George Hugh, Flight Sub-Lieutenant, R.N.A.S., drowned on patrol service in Italy on January 7th, aged 18 years. He was the only son of Dr. Percy C. Phillips of Abridge, Essex, and joined the R.N.A.S. in April, 1917.

MEDICAL STUDENTS.

Cameron, Robert, Lieutenant Royal Flying Corps, killed recently, aged 22. He was the only surviving son of Archibald Cameron of Langside, Glasgow, and was a medical student at Glasgow until the beginning of the war. He got a commission in the Cameronians (Scottish Rifles) on April 29th, 1915, and subsequently transferred to the R.F.C.

Sprott, Douglas A., Lieutenant Border Regiment, died in Mesopotamia on January 4th from acute yellow atrophy of the liver, aged 24. He was the eldest son of Dr. Sprott of Appleby, and was educated at Bedford College and Edinburgh University, where he was studying for the medical profession; at the outbreak of the war he received a commission in the Border Regiment, and went to Burma in October, 1914, and as machine gun instructor travelled over India and Burma. Three months ago he was sent to Mesopotamia as second in command of a machine gun corps.

Many medical men in this country will desire to express to Dr. Henri Triboulet, the Paris physician through whom the visit of the French doctors to this country in 1908 was arranged, their sympathy with him in the loss of his son, a distinguished officer of the French Air Service. Adjutant Gilbert Triboulet had engaged in forty-eight air combats, had brought down three enemy airplanes and three captive balloons, and had received the Military Medal and the Croix de Guerre with four bars. He was killed on patrol duty on December 11th, 1917, aged 22.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL supplement to the *London Gazette*, issued on January 9th, gave the following particulars of the acts of conspicuous gallantry and devotion to duty for which the decorations announced in our issue of October 6th, 1917, were awarded:

Bar to the Distinguished Service Order.

Major James Samuel Ycaman Rogers, D.S.O., R.A.M.C.

Throughout several days' operations he attended to the wounded in the open under continuous heavy fire. Though all his stretcher-bearers were casualties, with utter disregard of danger he bound up the wounded and superintended their removal. His gallantry was most marked. (D.S.O. gazetted January 14th, 1918.)

Distinguished Service Order.

Major (temporary Lieut.-Colonel) Edwin Charles Montgomery-Smith, R.A.M.C.

For conspicuous gallantry and devotion to duty in the supervision of the arrangements for the evacuation of the wounded. By a systematic study of the ground, clever selection of aid and relay posts and routes, he evacuated a large number of casualties during the operations. He worked untiringly, regardless of his personal safety, visiting all the advanced aid posts. His work was invaluable.

Captain (acting Lieut.-Colonel) John Darling Bowie, M.B., R.A.M.C.

He worked continuously for thirty-six hours under heavy shell fire, supervising the removal of the wounded from the front line, and by his energetic example and personal assistance all casualties were cleared within a short time after the operations were completed. His disregard of danger and untiring devotion to duty had a splendid effect upon his men.

Temporary Captain John Boyd Orr, M.C., M.B., R.A.M.C.

He worked unceasingly for forty-eight hours without an aid post and under an almost continuous barrage, attending to the wounded of three units of his brigade. He found time to visit the front line twice and attended to numerous cases under machine gun and shell fire, and, although twice buried and rendered unconscious for two

or three hours, he remained at duty until his brigade was relieved, displaying devotion and personal courage which were worthy of the highest praise. His gallant conduct has been brought to notice on more than one occasion by officers commanding units to whose wounded he had attended.

Temporary Captain David Lees, M.B., R.A.M.C.

He passed through an intense barrage in order to attend to the wounded who were lying exposed to heavy fire of every description. Single-headed and under heavy shelling, he dressed the wounds of an officer, a sergeant, and a private, and carried each of them in turn to a place of comparative safety. To do this he had to pass through the enemy's barrage no less than four times, but with complete disregard for his personal safety he went forward a fifth time to attend to others, inspiring all ranks by his own splendid example of fearlessness and devotion.

Temporary Captain Ivan Clarkson Maclean, M.C., R.A.M.C.

For conspicuous gallantry and devotion to duty in clearing the wounded. He took his stretcher-bearers well in advance of our forward positions and behaved with the most exemplary courage and devotion throughout, sparing no efforts to collect the wounded men. After his battalion was relieved he continued to work under the heaviest fire for another twenty-four hours, and was severely wounded on his way back after all the cases had been cleared. He set a splendid example of energy and contempt of danger.

Temporary Captain Hnbert Arnold Pallant, M.C., R.A.M.C.

Hearing that a number of men belonging to another battalion were on the enemy bank of a river, and unable to cross it owing to the bridge being destroyed, and to their being apparently unable to swim, he hurried to the scene, swam the river fully clothed, and induced the men to enter the water and cross with the aid of a rope. The most exhausted one he personally conveyed across. During this time the enemy were continually shelling both the river and the banks. He set a splendid example of energy and devotion to duty.

Temporary Captain Gwilym David Watkins, R.A.M.C.

When cries for help were heard coming from a tank which had been abandoned in an isolated position in the outpost line he went two hundred yards through a heavy barrage and rescued a badly wounded man from the tank. He dressed his wounds and carried him under heavy fire towards safety, until, being completely exhausted, he was compelled to put the man in a shell hole and go for assistance. He returned with another officer, and, still under heavy fire, brought the man to safety. Throughout six days he displayed the same indomitable courage and extraordinary devotion to duty, constantly going into the open, tending the wounded day and night. He undoubtedly saved many lives.

Bar to the Military Cross.

Captain William Barnsley Allen, V.C., M.C., R.A.M.C.

During an intense bombardment of a town with high explosive and gas shells, he left the advance dressing station to search for wounded men. Hearing that there were some in a remote part of the town, he proceeded there, collected them, and supervised their removal to the dressing station. On his return, bearing that a party under another officer had not come in, he was on the point of starting out again to look for them when they appeared. Although seriously gassed he continued to perform his duties with the greatest devotion and gallantry, until eventually evacuated to the casualty clearing station. (M.C. gazetted September 26th, 1916.)

Captain Hugh Roger Partridge, M.C., R.A.M.C.

During an intense bombardment of a town with high explosive and gas shells he led search parties into different parts of the town, collecting the wounded and placing them in a cellar, where he attended to them. Later, when the bombardment subsided, he superintended their removal to the advanced dressing station. On his return to the dressing station he continued to perform his duties, although his eyes were so swollen by gas that he was obliged to keep them open with his fingers. He undoubtedly saved several lives by his splendid devotion and total disregard of personal danger. He was eventually evacuated to the casualty clearing station. (M.C. gazetted October 26th, 1917.)

Captain John Dover Proud, M.C., R.A.M.C. (S.R.).

He worked for five days in charge of bearers practically without rest, personally assisting to evacuate stretcher cases under the heaviest shell fire, thus setting an example of gallantry and devotion to duty under most arduous circumstances. (M.C. gazetted June 18th, 1917.)

Temporary Captain Robert Inkerman Harris, M.C., M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty under exceptional circumstances. When his corps main dressing station was shelled on three separate occasions, whilst crowded with patients, he supervised and directed the collection and evacuation of the wounded to a place of safety. This was quickly done owing to his coolness, promptitude, and disregard of personal danger, which did away with all confusion and reduced the casualties to a minimum. (M.C. gazetted November 14th, 1916.)

Temporary Captain Wilfred McFarlane, M.C., M.B., R.A.M.C.

He carried on his work for five days under very heavy shell fire. His coolness under fire, his absolute disregard of danger, and his cheerfulness under all circumstances set a fine example to all ranks, and contributed greatly to the successful evacuation of the wounded. (M.C. gazetted December 11th, 1916.)

Temporary Lieutenant (Temporary Captain) Lancelot Gerard Bourdillon, D.S.O., M.C., R.A.M.C.

For conspicuous gallantry and devotion to duty on numerous occasions. He worked continuously for many days, organizing stretcher-bearers and forming relay posts. This work was carried out under very heavy artillery and machine gun fire, during which he showed an absolute disregard of personal danger and set a splendid example to all the officers and men employed on stretcher work. It was largely due to his devotion that many lives were saved. (M.C. gazetted January 14th, 1916.)

Military Cross.

Captain Cuthbert Delavel Shatto Agassiz, M.B., R.A.M.C.

He worked continuously for thirty hours organizing his stretcher-bearers and collecting wounded from an area which was being constantly and heavily shelled. On three distinct occasions he had to go through the hostile barrage in order to do this, and, although working the whole time over marshy and waterlogged ground, he

kept such control over his men by his personal example of courage and coolness under most dangerous conditions that the wounded were successfully and rapidly evacuated.

Captain Arthur Cyril Bateman, R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty in repeatedly going round the front line and attending to the wounded, who had been lying out in some cases for two days. Although continuously exposed to hostile sniping and machine gun fire, he displayed the utmost disregard of danger.

Captain Kenneth Biggs, R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty in leading and organizing his stretcher-bearers, under intense fire of every description, in such a manner that our wounded were rapidly evacuated. He worked unceasingly in the open for twenty-four hours, until he was severely wounded, by his admirable courage and determination saving many lives.

Captain Ribton Gore Blair, M.B., R.A.M.C. (S.R.).

When his battery was heavily shelled, and the detachment of one gun had been either killed or wounded, he immediately went to the emplacement and dressed the wounded under heavy fire. It was owing to his gallant and fearless conduct on this occasion that the lives of many men were saved.

Captain Francis Dawson Blandy, M.D., R.A.M.C.

He worked continuously for thirty-six hours under heavy shell fire and adverse conditions of weather, not only collecting the wounded of his own brigade, but also those of another, who were lying in an advanced position. To do this he collected all the bearer parties that he could find, and personally led them to the spots under heavy shell fire. By his gallant conduct in going forward again and again, regardless of his personal safety, he undoubtedly saved many lives.

Captain Thomas Frederick Corkill, R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty when in charge of a forward bearer party. He worked continually for four days under heavy shell fire, evacuating the wounded and setting his men a magnificent example of courage and disregard of danger. He personally led parties beyond the advanced aid post to collect the wounded, and his great zeal and energy enabled him to overcome very serious transport difficulties.

Captain William Ernest FitzGerald, M.B., R.A.M.C.

In attending to wounded and gassed men during a heavy gas shell bombardment. To do so he had to remove his mask, although he knew the risk, and was badly gassed in consequence. Although suffering badly from the gas, he remained on duty until the following day, when he was ordered to the dressing station, having displayed magnificent pluck and devotion to duty.

Captain John Canute Gordon Glassford, Australian Army Medical Corps.

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. He continued to work calmly for several hours under violent and accurate hostile fire, during which his dug-out was three times hit and considerably damaged. Throughout the operations he displayed a magnificent example of gallantry and devotion to duty and inspired all under him with a like disregard of personal risk. Much of his work was done in the open and under very trying and dangerous conditions, but the cheerfulness and imperturbability which he maintained in the face of danger were of the greatest assistance in the speedy evacuation of the wounded.

Captain Herbert Myer Goldstein, New Zealand Medical Corps.

For conspicuous gallantry and devotion to duty in establishing a forward aid post in our advanced lines over a mile in front of his regimental aid post. By his courageous decision to remain there in spite of heavy shelling, and his great gallantry and devotion in attending to the wounded, all the casualties were evacuated before the battalion was relieved.

Captain Gilbert William Rogers, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded under heavy shell fire. He personally supervised the evacuation of the wounded, and by his ability and utter disregard of his own personal safety was able to ensure the work being rapidly and successfully carried out. He set a splendid example to all ranks.

Captain James Ellis Rusby, R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty whilst acting as bearer officer during five days' heavy fighting. He led a party of stretcher-bearers through an intense artillery barrage, inspiring them and giving them courage by his own gallant and fearless example. Several of his men were wounded whilst passing through the barrage, and he stopped to dress them himself, although shells were falling all around. On many occasions he attended the wounded in the open, although exposed to very heavy shelling, very greatly inspiring his men by his personal coolness and disregard of danger.

Captain Herbert Mather Spoor, R.A.M.C.

Under an intense hostile bombardment he dashed out of a cellar, where he was sheltering, and ran across the open to attend to two men who had been wounded in a dug-out. After attending to them, he noticed that the house he had just left was hit, whereupon he ran back again through heavy shell fire to see if his services were required. He displayed splendid gallantry and total disregard of his personal safety.

Captain Robert Alexander Stark, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station under an intense bombardment. He worked steadily for over twelve hours, and, although seriously affected by gas, did not complain, until he finally collapsed from the effects, and was found lying on the ground. He personally supervised the clearing of a thousand cases, and it was largely due to his splendid self-sacrifice and devotion that the complete and successful evacuation of the casualties was effected.

Captain John Stephenson, R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty when in charge of stretcher-bearers. He remained in charge of his sector for thirteen days, refusing to be relieved, although his bearers had to be reinforced and the aid post had to constantly change position owing to heavy shell fire. His personal example and gallant leadership were largely responsible for the way in which his bearers stuck to their duty.

(To be continued.)

MENTIONED IN DISPATCHES.

A special Supplement to the *London Gazette* issued on January 12th contains a list of officers, ladies, non-commissioned officers and men mentioned by General Sir Archibald Murray, K.C.B., late Commander-in-Chief Egyptian Expeditionary Force, in accordance with the concluding paragraph of his dispatch dated June 28th, for gallant or distinguished conduct in the field or for other valuable services. The following medical officers are included in the list:

Staff.

Colonels: R. M. Downes, A.A.M.C., H. T. Knaggs, C.M.G., A.M.S., R. H. Luce, C.B., F.R.C.S., V.D.(T.F.Res.), C. J. MacDonald, A.M.S.

Lieut.-Colonel (temporary Colonel) A. E. C. Koble, D.S.O., R.A.M.C.

Major (temporary Lieut.-Colonel) M. W. Cave, A.A.M.C., Captain J. H. Wood, R.A.M.C.

Royal Army Medical Corps.

Lieut.-Colonel E. E. Powell.

Majors (temporary Lieut.-Colonels): R. J. Cahill, A. W. Moore, C. R. White.

Captain (temporary Major) W. W. Greer.

Captains: H. J. L. Barefoot, D. W. Berry, E. D. Gairdner, D.S.O., W. Goldie, H. F. G. Hall, E. B. Hinde, C. W. C. Myles, N. MacInnes, D. J. Marr, J. M. Mitchell, P. J. Moir, A. Rankine, A. B. Sloan, C. F. Searle.

Temporary Captains: R. R. Archibald, J. T. Blesdell, O. Bruce, W. T. Collier, H. Coppock, H. S. de Boer, N. Duggan, J. W. C. Gunn, D. L. Hutton, J. M. Johnston, C. Loddiges, G. Wight.

Temporary Lieutenants: C. Speers, F. J. Waldmeier.

Special List.

Temporary Lieut.-Colonel L. P. Phillips.

Australian Army Medical Corps.

Lieut.-Colonel A. H. Thwaites.

Majors: W. Evans, W. R. C. Mainwaring, E. K. Parry.

New Zealand Medical Corps.

Lieut.-Colonel C. T. H. Newton.

Indian Subordinate Medical Department.

Subassistent Surgeons Kapar Karamchand, and Puroshottam Damodar Mahatekar.

The list also contains the names of 30 warrant, non-commissioned officers and privates of the R.A.M.C., 5 of the A.A.M.C., 1 of the N.Z.M.C., 2 of the I.S.M.D., as well as members of the nursing services.

ORDER OF THE BRITISH EMPIRE.

The name of Colonel Valentine Matthews, V.D., Inspector of Rest Houses, London District, was accidentally omitted from the list of appointments to be Commanders of the Order of the British Empire published last week, p. 67.

FOREIGN DECORATIONS.

Russian decorations have been awarded at various dates to the following medical officers for distinguished services rendered during the course of the campaign:

Order of St. Stanislas.—1st Class: Surgeon-General J. D. Edge, C.B., A.M.S. 2nd Class: Lieut.-Colonel W. W. O. Beveridge, C.B., D.S.O., R.A.M.C.; Temporary Major L. E. Owen, R.A.M.C. 3rd Class (with swords): Temporary Captain T. J. Kelly, M.C., R.A.M.C.

Order of St. Anne.—2nd Class (with swords): Acting Colonel H. Hewetson, D.S.O., R.A.M.C. 3rd Class: Temporary Captain A. H. Spicer, R.A.M.C.

England and Wales.

CHILD WELFARE AND A MINISTRY OF HEALTH.

On January 9th the President of the Local Government Board received a deputation representing the local authorities of England and Wales, which urged that the powers affecting maternity and infant welfare administration now possessed by local authorities in Scotland and Ireland should be extended to England and Wales. It was explained that there was no objection to the proposal for a Ministry of Health, but that if a consolidation of the various Government departments concerned was to be developed into a central authority, this authority ought to be the Local Government Board. Mr. Hayes Fisher, in reply, noted that there was no difference of opinion as to the urgent necessity for saving infant life; it was merely a question of the order of going. Without prejudice to the larger question of setting up a Ministry of Health, he believed that a small bill giving the required powers could be passed without opposition. Many months must elapse before a measure establishing a Ministry of Health could reach the statute book and the organization of such a department could be developed. The Local Government Board was anxious to push forward the prevention and cure

of disease, so that mothers might bring infants into the world without imperilling their own lives or those of their offspring. He believed that, building on the foundations of the Local Government Board, a central co-ordinating health authority could in time be systematized and developed. Dr. Addison, Minister of Reconstruction, who followed, stated that he had now got out a complete statement of the amazing number of Government departments concerned with health questions. The great need was for concentration and consolidation. With a single Minister in charge, the subject in which the deputation was interested would have a far better prospect of being considered on its merits. The Minister's duty would be to think out details of health policy and discuss them with representatives of the local bodies. It was inconceivable that a Ministry of Health could be formed that did not exercise nine-tenths of the functions of the Local Government Board; hence the Board must necessarily be the nucleus. In his opinion a brand-new Ministry was not needed. All that was wanted for the solution of the problem was a little common sense. Dr. Addison concluded by inviting the deputation to select a few of their number to discuss the matter with him.

In the *Times* of the following day appeared a letter from a group of ten members of Parliament, headed by Major Waldorf Astor, advocating the combination and reorganization of existing departments for the setting up of a Ministry of Health, and submitting the heads of a bill for the purpose. Their suggestion is that so soon as the new Ministry has been established by Parliament all the powers of the National Health Insurance Commissions for England and Wales, and all the powers of the Local Government Board should be transferred to it by Order in Council. In the same way the health functions of other departments would be taken over at such times as were found convenient. They propose also that there should be power to transfer from the new Ministry to other departments any functions transferred to it at first for the sake of convenience but found to be unsuitable for a Health Ministry to perform. In other words, the new Ministry would be simultaneously acquiring and shedding powers; this is a clumsy mode of proceeding, but the promoters advise it because they think that by this expedient matters of national health will be discussed on their merits undisturbed by the conflicting claims of rival authorities. Mr. Hayes Fisher immediately objected that such a measure would probably require a considerable amount of parliamentary time which might not be available in the coming session, and urged that a small bill to confer on local authorities the wider powers in regard to infant welfare, for which they unanimously asked, would stand a better chance; but he agreed that there was a good deal to be said in favour of bringing all health questions as far as practicable under one minister. Sir H. Kingsley Wood, of the London Insurance Committee, who has interested himself very much in the establishment of a Ministry of Health, read into the scheme of Major Astor and his friends the suggestion that they desired a Board of Health which would be able effectively to advise the Health Minister and to be a living link with local health administration; he showed himself very anxious to make it plain that such a Ministry would not mean the break up of the useful work of the county councils. His proposal he said would, in fact, concern central administration only, by unifying it, leaving the work of the local councils untouched and unimpaired. Then came Lord George Hamilton, who contended that the necessary preliminary to any local co-ordination of health powers is the abolition of the Poor Law guardians and their artificial areas of administration, and the transfer of their powers to the existing county or borough authorities. He argued that the Poor Law guardians are to a large extent entrusted with the care of the health of the poor, are solely in charge of the administration of the hospitals and infirmaries maintained out of the rates, and have a "singularly efficient staff, whose activities are hopelessly hampered by the existing prejudice against the organization to which they belong." The proposals he adumbrated have, he says, the unanimous approval of the Royal Commission upon the Poor Law, of which he was chairman, although there was difference of opinion as to the exact machinery to be substituted for the system they desired to abolish.

It is stated that the Local Government Subcommittee, of which we believe Sir Donald Maclean is chairman, of the

Committee of Reconstruction under the charge of Dr. Addison, has made a report recommending "the abolition of boards of guardians, a great reform of the Poor Law, and a rearrangement of the medical services of the country." The report, it is stated, was under the consideration of the Poor Law Association on January 17th.

THE LEEDS SCHOOL OF MEDICINE.

The Department of Physiology in the University of Leeds, so ably conducted by Professor de Burgh Birch until his recent retirement after more than thirty years' tenure of his chair, is now about to undergo extension. The work of the teachers of physiology has been divided: Dr. H. S. Raper becomes professor of physiology and biochemistry, and Dr. C. Lovatt Evans has been appointed to a new chair of experimental physiology, or, as it will probably be called, "experimental physiology and experimental pharmacology." It is becoming more and more evident that an increasing contribution to the progress of medicine and surgery is possible through a more detailed study of the chemical processes in health and disease, and the influence upon them of drugs and substances of known chemical composition. An example of this is furnished by the recent investigation of the antiseptic action of many substances containing active chlorine, which was undertaken early in the war by the department of organic chemistry of this university in conjunction with Dr. H. D. Dakin, F.R.S., a former student and member of the staff. These researches led to the introduction of chloramine-T and dichloramine-T, which are widely used in the treatment of war wounds. To carry out efficiently the new schemes increased accommodation will be necessary, chiefly in the form of additional laboratories for research. Considerable additions to the apparatus at present in the Department of Physiology must also be provided. The Council of the University has under consideration also a draft scheme for the extension of the teaching in pathology and bacteriology.

Professor Raper, after being a pupil of the Bradford Technical College, went to the University of Leeds as a student of science in 1899. He had a distinguished career, and during his tenure of an 1851 exhibition scholarship was engaged in research for two years at the Lister Institute and for one year at the University of Strassburg. He graduated M.B., Ch.B. Leeds in 1910, in which year he was appointed lecturer on pathological chemistry at the University of Toronto; in 1913 he became lecturer on physiological chemistry at Leeds. He is now on military service. Professor Lovatt Evans, who is also on military service, began work at Birmingham, but afterwards became a student at University College, London. In 1911 he was elected Sharpey scholar and assistant professor. He graduated D.Sc. in 1913 and took the diplomas of M.R.C.S., L.R.C.P. in 1916. In the previous year he had received the Schäfer prize at University College for the best research work during the three years 1911-14.

PUBLIC HEALTH (TUBERCULOSIS) REGULATIONS, 1917.

The Local Government Board announces that an Order has been made altering the Public Health (Tuberculosis) Regulations of 1912 and 1916 so as to provide that medical officers of health, instead of furnishing the Army Council with particulars of males between the ages of 16 and 45 years who have been notified as suffering from tuberculosis, shall in future furnish such particulars to the Chief Commissioner of Medical Services at the Ministry of National Service. The object of the Order is to assist the Ministry of National Service, which has taken over the duties of the Army Council with respect to enlistment into the army. The operation of the Order is limited to the duration of the present war. Notifications should be forwarded by post in a sealed envelope, which need not be stamped, and marked "O.H.M.S."

AN AMATEUR SYPHILOLOGIST.

At a meeting of the Denbighshire Insurance Committee, on January 2nd, of which a report appears in the *North Wales Guardian*, Dr. E. Moss, chairman of the Local Medical and Panel Committee, brought forward the following matter: Dr. Richard Evans, of Wrexham, attended last year a female patient whom he certified to be suffering from rheumatism. She was an insured person, and as such was reported by the sick visitor for being out late at night, for which offence her sickness benefit was suspended for a time. Subsequently she was seen by a woman supervisor of the approved society, who coolly reported "that the patient is supposed to be

suffering from rheumatism, as appears on the medical certificate, but I find that she is suffering from syphilis." This amateur diagnostician gave the date at which symptoms of "syphilis" appeared, and added that she had examined the breast and upper arms of the patient. Meanwhile, Dr. Evans was attending the patient regularly. The approved society next asked a medical referee to see the insured person. The referee, who was furnished with a copy of the supervisor's report, examined the patient and formed the opinion that she was not suffering from syphilis, thus confirming the view taken by Dr. Evans. In the course of a long correspondence between Dr. Evans and the society the latter expressed regret, but offered no apology, nor any guarantee against the recurrence of such an incident. Indeed, they argued that if Dr. Evans had stated in his first certificate what he did in his later ones—namely, that the patient was also suffering from psoriasis, the whole trouble would have been avoided. Dr. Moss submitted that there was ample evidence to show that the supervisor had violated the spirit of the society's instructions, while the society itself was guilty of want of courtesy towards Dr. Evans. The chairman said the case was a very regrettable one, but for the time being the only thing for the Insurance Committee to do would be to refer the matter to the Welsh Insurance Commissioners. This was agreed to.

Ireland.

At a meeting held at the Royal College of Surgeons on January 11th, when Mr. J. B. Story, vice-president of the College, was in the chair, a presentation was made by leading members of the medical profession in Dublin to Surgeon-General Sir Richard Ford, K.C.M.G., who has just relinquished the appointment of D.D.M.S. Irish Command. The presentation took the form of a replica of the famous Ardagh chalice. An address was read by the honorary secretary, and Sir Richard Ford replied. Lady Ford was presented with a silver chain bag and a blotter illuminated with the R.A.M.C. badge and other devices, the work of a wounded soldier in one of the Dublin hospitals.

GRADED SCALES OF SALARIES FOR POOR LAW MEDICAL OFFICERS.

Acting on the suggestions of the Local Government Board (Ireland) the Cork board of guardians has modified the scale of graded salaries it passed last August for Poor Law medical officers. The amended scale provides an initial salary for a dispensary medical officer of £175 a year, made up of £150 for dispensary duties and £25 for duties as medical officer of health for the district. There are annual increments of £4 until a maximum of £210 a year is reached in the salaries of dispensary doctors, and an increment of £1 annually until a maximum of £40 is reached in their salaries as medical officers of health of their dispensary districts. The present scale adopted by the Cork guardians is a very substantial improvement on the scale they fixed some dozen years ago.

The Mallow board of guardians has amended its scale, and now the initial salary is £140 a year for dispensary doctors, with triennial increments of £10 until a maximum of £200 a year is reached; the scale is made to apply retrospectively. On December 29th we mentioned that the Newcastle West (co. Limerick) board of guardians having rescinded, by a majority, a recent increase, the Poor Law medical officers at once sent in their resignations. The guardians have now resolved to offer an initial scale of £130 with triennial increments of £10 until a maximum of £180 is reached, the scale to apply retrospectively. This is undoubtedly a tribute to the vigorous action taken by the Newcastle doctors; it is, however, stated that they decline to accept the scale offered by the guardians until a further substantial improvement is made.

THE RED CROSS.

The result of the appeal made in September, 1915, by the *Irish Times* to raise £50,000 for the Red Cross has been gifts amounting on January 5th to £51,834. Very energetic means were taken to arouse interest in the fund. A house to house collection of copper and brass was made in Dublin, and a jewellery collection yielded £2,000. During the Christmas holidays all the Irish golf clubs had competitions, the proceeds of which were given to the fund, and collections were made in the churches on the first Sunday in 1917. All sections of the community have responded well, and it is hoped that when the fund is closed at the end of January it will amount to £60,000.

Correspondence.

THE VALUE OF THE SANATORIUM.

SIR.—Whilst the numerous letters, reports, and articles in the medical press were dealing with the question of the value of sanatorium treatment for the cases treated, the conclusions formed had their appropriate value; but when we find the field widened and these conclusions embodied in a statement dealing with the incidence of tuberculosis, it seems desirable to draw attention to the realities of the subject.

The problem of dealing with tuberculosis is many-sided, but, put briefly, the objects are to restore the health and working capacity of the affected person as far as possible, to limit infection and protect the general population. For these purposes many measures are necessary, and the first is to have adequate knowledge of the presence of disease. This is provided for by the tuberculosis notification order, and from the information gained in its observance all effective procedures must issue. Upon the action taken depends the efficacy of any scheme dealing with tuberculosis, and the provisions made should enable the tuberculosis officer to keep in touch with all the notified cases in a district, in order that he may direct the action referred to in such a way that the best interests of the patient and the community are served.

The success of a scheme depends upon the completeness with which this is effected. To those of us who were engaged in this work before the coming of the Insurance Act the provisions there made gave a welcome addition to this necessary control, and brought in the very valuable clinical information supplied by the panel practitioners. But there were unfortunate features of the campaign that preceded the passing of the bill, and a great deal too much was made of the sanatorium treatment clauses. Reckless statements, promises which were obviously impossible of fulfilment, and a general raising of hopes were to be noted as part of the political stock-in-trade of the time. There follows now a disappointment which is great in proportion to the ignorance which at the time allowed credence to be given to the statements. And, as some one has blundered, a movement is in danger of being discredited because it could not accomplish the impossible.

Why should it be sanatorium treatment that has failed? It is but an incident in the usual life-history of a case of tuberculosis. Why is it not dispensary treatment that has failed—or domiciliary treatment—under one or other of which most of the medical life of a patient is spent? Let us realize the true facts of the case. What has failed is public realization of the extent to which the country must be prepared to finance the campaign against tuberculosis if its elimination is desired. The nation must be prepared to provide conditions of housing and work that will not directly contribute to the contraction of tubercle. There must be colonies in which the afflicted persons, unfit for the rough-and-tumble of ordinary industry, may reside and work under the most ideal conditions, so that they become a source of production instead of a maintenance charge. There will have to be provided hospital accommodation for the advanced cases on a sufficiently generous scale to alter appreciably the present ratio of institutional to domiciliary deaths. And there should be sanatoriums to fulfil their main functions of inculcating the necessity of a disciplined life and starting the patient with early disease upon the road to recovery of his resisting powers.

These various elements in the campaign should be co-ordinated by an experienced tuberculosis officer who is in touch with the profession, public health office, and the charitable and hospital organizations of the area. Each unit of the scheme should have its true value given to it, and no one form of treatment need be played off against another. Each has its appropriate function to fulfil, each item is necessary, and progress will depend upon the extent to which the fullest use is made of every combative measure directed against those conditions which break down mankind's resisting power. The attempt to produce immunity need not limit our efforts to diminish the incidence of infection, and if tuberculinization must go on, at least we can see to it that it shall not proceed in advance of a capacity for resistance.—I am, etc.,

Manchester, Jan. 5th.

D. P. SUTHERLAND.

HOW IS THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS TO BE MADE?

SIR,—I think a very satisfactory answer to this question can be obtained from the "precipitin" test evolved by Carl Spengler of Davos. By means of this test, correctly interpreted, the following conclusions can be drawn:

1. Whether the patient is in a pretuberculous state or one likely to develop into phthisis.
2. Whether the patient is phthisical—that is, in a state in which the immunizing bodies in the blood are below safety.
3. If phthisical, whether the infection is due to the true bovine type of bacillus or the Koch (*brevis*) type.
4. A very good idea as to prognosis.

Subsequent tests are, of course, desirable, and enhance the value of any deductions made.

Another very important factor is the use of satisfactory methods of staining sputum, etc. By the ordinary Ziehl-Neelsen method bacilli are not infrequently missed. By Spengler's combine 1 carbol-fuchsin and picric acid method, and by his structural method staining with osmic acid vapour much valuable information may be gained. Spengler has demonstrated that the tubercle bacillus is composed of a sheath, and contains granules which are stained black by the osmic acid method. When a case of tuberculous infection is doing well and the patient's blood is rich in immune bodies, the sheath is broken and these contained granules are set free as individual bodies, which he has termed *Splitter*. Furthermore, he has shown that these splitter bodies are capable, under suitable conditions, of developing into tubercle bacilli. From this it is obvious that the detection of their presence is a valuable aid both to prognosis and diagnosis.

It might be argued that when the bacilli are capable of being demonstrated in sputum the case is not an early one. This is true, but less true if the method used to detect them is superior to the commonest one in vogue at the present time. In any case it does not detract from the value of the precipitation test.

For the details of the technique in performing the test and the methods of staining, reference can be made to Spengler's own publication, *Tuberculosc. und Syphilis-Arbeiten*, or to *I.K. Therapy*, by W. E. M. Armstrong, M.A., M.D. (Dubl. H. K. Lewis), or to *Tuberculosis and the Immune Substances Therapy*, by W. H. Fearis (John Murray).—I am, etc.,

Newick, Jan. 2nd.

J. CHASLEY MACKWOOD.

SIR.—I desire to add to Mr. E. D. D. Davis's letter in your issue of December 29th, 1917, the description of a method which I have adopted for some time, and which will appeal, I am sure, to him and to our fellow laryngologists.

In doubtful cases of laryngitis in which I have had suspicions of the condition being tuberculous I have frequently been able to procure immediately a satisfactory specimen of sputum by syringing a small quantity of a weak solution of sodium bicarbonate into the larynx and trachea with an intralaryngeal syringe. This may pass muster as merely "washing out the larynx." The patient then coughs vigorously, and in many cases can be induced to eject the liquid with a pellet of sputum into a basin. This proceeding is often invaluable in those not uncommon cases in which the secretion is inconsiderable and habitually swallowed by the patient instead of being coughed out. In these cases the patient, when asked to bring his morning sputum, produces as often as not a specimen of frothy saliva from the mouth. Again, in the case of very anxious patients the sputum may be obtained in this manner without their being alarmed by the suggestion of the possibility of tuberculosis.

More recently I have employed a simpler method. It consists in causing the patient to inhale the vapour of mustard oil. A few drops of strong aromatic oil of mustard are poured into an empty 6 or 8 oz. bottle. This may be corked up for about a minute to allow the vapour to fill the bottle, which may also be held for a few moments over a lamp. It is then uncorked, and the patient is instructed to take "a good sniff" of it. After one or more good sniffs he generally begins to cough, and may be induced to expectorate any secretion that may be present in the larynx or trachea. If no cough takes place, I think the probability of the existence of tubercle of the larynx at least is slight.

In several instances I have by these means been able to obtain fair specimens of sputum containing bacilli in which no physical signs of pulmonary tuberculosis were detectable, even in some in which the "morning sputum" was negative, being probably not a fair specimen.—I am, etc.,
London, W., Jan. 5th. DUNDAS GRANT.

THE PULSE PRESSURE TEST BEFORE OPERATIONS.

SIR,—I am sorry to see you give such prominence to "the pulse pressure test before operations" in the *JOURNAL* for January 5th, p. 26. Beyond supplying the force that causes the blood pressure the heart takes little part in the variations that occur, and the factors concerned in regulating the changes in blood pressure are so obscure that observations drawn from them are little better than guess-work. So many bogeys have been raised at one time or another about the heart being unable to stand anaesthetics that much confusion prevails, and the addition of this fallacious blood pressure claim cannot but add to the confusion.—I am, etc.,

London, W., Jan. 10th.

J. MACKENZIE.

* Sir James Mackenzie's opinion naturally carries great weight, but it does not appear from his letter whether or not he has read Cashman's article "On the pulse pressure test in pre-operative estimation of the reserve strength of the cardio-vascular system," which, in our humble opinion, justifies further investigation.

WAR NEPHRITIS.

SIR,—The letter by Captain Hendry in your issue of January 5th, p. 37, calls for comment. Trench fever and war nephritis have hitherto been regarded, on clinical and pathological grounds, as separate entities.

The term "trench fever" has been loosely applied to cases of pyrexia associated with a variety of symptoms of different etiology. What does Captain Hendry mean when he writes of trench fever?

We find his evidence as to the occurrence of nephritis in his series unconvincing. Profuse haematuria certainly can, and frequently does, occur in war nephritis without pre-existing trench fever. We have seen many cases of "P.U.O." in which the early provisional diagnosis of nephritis has had to be discarded on fuller inquiry. It is a common experience to find slight albuminuria, with the occurrence of a few blood corpuscles and endothelial cells, in the early stage of trench fever, and these may recur with each subsequent rise of temperature. In none of our cases, however, has there been any rise of blood pressure, dyspnoea, or any uraemic symptoms; in the absence of these, and in view of the transient nature of the albuminuria these cases cannot be regarded as nephritis. We are in agreement with Captain Hendry's statement that the cure of shin pains in most cases is slow; we are in complete disagreement with him when he suggests that the symptoms of trench fever and war nephritis are members of the symptom-group of one and the same disease.

It seems a pity that confusion should be introduced by the suggestion that these two diseases are related to each other—a suggestion for which, in our opinion, no satisfactory basis has yet been forthcoming.—We are, etc.,

C. E. SUNDELL,
Captain R.A.M.C.

A. T. NANKIVELL,
Captain R.A.M.C.

Stationary Hospital, B.E.F.,
January 10th.

VINCENT'S ANGINA AND PERIDENTAL GINGIVITIS.

SIR,—In their memorandum which appeared in the *BRITISH MEDICAL JOURNAL* for January 5th, Captains Eagleton, Mercer, and Hudson, of the Royal Army Medical Corps, express surprise that in the various articles on the prevalence of Vincent's angina, both amongst our overseas troops and amongst the home service units, they can find no mention of the condition of the gums in this infection.

May we be allowed to point out that this condition was very carefully and thoroughly described by us in a paper on "Fuso-spirillary peridental gingivitis," read before the

Odontological Section of the Royal Society of Medicine on November 27th, 1916, and published in the *Proceedings* of the Society for that date? In this paper, also, the differential diagnosis of fuso-spirillary peridental gingivitis and pyorrhoea is discussed, much confusion having resulted from the laxity with which the term "pyorrhoea" has often been employed. We agree with Captains Eagleton, Mercer, and Hudson that these two conditions may coexist.

The connexion between Vincent's angina and this condition of the gums was fully dealt with in a further paper by us on "The relation of peridental gingivitis to Vincent's angina," read before the Laryngological Section of the Royal Society of Medicine on February 2nd, 1917, appearing in the *Proceedings* of the society and also in the *BRITISH MEDICAL JOURNAL* for March 31st, 1917.

How thoroughly Captains Eagleton, Mercer, and Hudson's experience confirms our previous findings is shown by the final paragraph of our second paper quoted above, in which we stated that "as the result of our investigations we suggest that when a patient complains of a sore throat which presents the characters of Vincent's angina it is essential to examine the tooth margins for evidence of peridental gingivitis or pyorrhoea, and that smears be made from both sources for the detection of the causal organisms. When found to be present, the peridental gingivitis should be adequately treated as well as the Vincent's angina, otherwise the condition is likely to persist indefinitely and to cause repeated recurrence of the sore throat."—We are, etc.,

FRANK E. TAYLOR, M.D., F.R.C.S., D.P.H.,

W. H. MCKINSTRY, M.D., D.P.H.,

Captain R.A.M.C.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—I read with deep sympathy the letter of "J. A. A." in your issue of January 12th.

There are many such cases, my own son, a first year student at Cambridge, among them. Within a stone's throw of my house a fellow student, a pacifist, has just become qualified.

Cannot something be done for these lads who have so bravely borne the hardships and given so much for their country? Many showed great talent too.—I am, etc.,

January 15th.

A PARENT.

The Services.

THE DIRECTOR-GENERALSHIP A.M.S.

RETIREMENT OF SIR ALFRED KEOGH, G.C.B.

THE Secretary of the War Office has issued the following communication:

"It is with great regret that the Secretary of State for War has decided that the time has come when Surgeon-General Sir Alfred Keogh, G.C.B., M.D., F.R.C.P., Director-General of Army Medical Services, must be permitted to resume his duties as General Executive Officer to the Imperial College of Science and Technology, and he will be replaced at the War Office from March 1st next by Colonel T. H. J. C. Goodwin, C.M.G., D.S.O., Royal Army Medical Corps, until recently the Assistant Director of Medical Services to the British Recruiting Mission in America, who will be appointed Acting Director-General of Army Medical Services.

"Sir Alfred Keogh's services were placed by the Governors of the Imperial College of Science and Technology at the disposal of the War Office at the beginning of the war, and although during the last three years they have on several occasions requested that he should return to his former duties owing to the development of matters of great national urgency which are delayed by his absence, it has not hitherto been possible to spare him.

"It is very largely due to Sir A. Keogh's intimate knowledge and grasp of all matters connected with the Army Medical Services and the medical profession generally that the medical needs of the army have been met to the fullest extent during the war, and he has been able to secure the assistance and advice of various committees of eminent consultants, which it is hoped will continue to be at the disposal of his successor."

Sir Alfred Keogh was born in 1857 and received his professional education at Queen's College, Cork, and Guy's

Hospital, London. He took the degrees of M.D. and M.S. at the Royal University of Ireland in 1878. After holding the appointment of house-physician at the Brompton Consumption Hospital he entered the medical department of the army in 1879, coming out second of nearly seventy successful candidates. This was the first batch of officers commissioned under the Warrant of 1879. For a considerable time before that the discontent in the service had been so acute that there had been the greatest difficulty in getting suitable men to come forward. At Netley Sir Alfred Keogh won the Martin Memorial Gold Medal and the Herbert Prize, and passed out with the highest total of marks of all the candidates—army, Indian, and naval. His first tour of foreign service was in Bermuda, whence he proceeded to India. On his return he was on duty at the Royal Arsenal, Woolwich, for five years; during that period he gained a large surgical experience. On completion of this appointment in the beginning of 1894 he was sent to India, where he served in the Madras Presidency; later he was transferred to Barrackpore, near Calcutta, where he was in charge of the Military Hospital. He was also civil surgeon there, and in that capacity had large opportunities of ordinary professional work among the operatives in the factories and civilian population. He returned to England in 1899, and in November went to South Africa as Secretary and Registrar of No. 3 General Hospital, which was at Rondebosch, near Capetown, in the early part of the war. When Bloemfontein was taken hospital accommodation was required on the lines of communication, and Colonel Keogh was sent to Springfontein with half of No. 3 General Hospital, and while there he was for a short time principal medical officer of the lines of communication from Bloemfontein to Norval's Pont.

He was soon transferred to Pretoria to take charge of No. 2 General Hospital, which he raised to a high state of efficiency. In November, 1900, it had 1,000 beds, and this number was maintained till the following March. He was also Senior Medical Officer of "Howitzer Camp," which included the Langman Hospital, and direction of the sanitation of the eastern outskirts of Pretoria. At the end of 1900 he contracted enteric fever, and was invalided home in February, 1901. He was mentioned in Lord Roberts's first dispatch, received the decoration of C.B., and was specially advanced from the lower to the higher rate of Lieutenant-Colonel.

When the reform of the Medical Service of the Army was undertaken, he was invited to join Mr. Brodrick's Reorganization Committee. His work as a member of that was of the highest value. He was appointed Deputy Director-General from January 1st, 1902.

On January 1st, 1905, he was appointed Director-General, and retained that office until 1910, when he was appointed Rector of the Imperial College of Science and Technology, South Kensington. During his first period of office as Director-General the medical service of the Territorial Force was organized, and the system of Territorial hospitals with staffs drawn from the civil hospitals in the various localities was brought into existence.

Colonel Goodwin is the son of Surgeon-Major J. Goodwin, A.M.S., and was born in Ceylon in 1871. He was educated at Newton College, Devon, and St. Mary's Hospital, London. He entered the Army Medical Service in 1893, passing out of Netley third of the batch. He served during the operations on the North-West Frontier of India in 1897 and was present during the operations against the Mohmands and in the action near Shabkadr, his services being rewarded by the D.S.O. He served with the British Expeditionary Force at Mons, the Marne, and Ypres; his services were three times mentioned in dispatches, and he received the C.M.G. in 1915. In the summer of that year he was the officer in command of No. 14 General Hospital at Wimereux. In May, 1917, he was appointed to accompany Mr. Balfour's mission to the United States of America as the representative of the Army Medical Department, where he has done much to facilitate the cordial co-operation between the medical profession in the United States and the British Army Medical Service.

THE late Dr. Thomas Tillyer Whiplam left £26,192.

A NEW weekly medical journal has recently been established at Milan. It is entitled *Il Medico Italiano* and is to be the organ of the Union of Medical Men for National Resistance and of the Sanitary Association.

THE French Government has appointed M. Paul Strauss, Senator and Member of the Paris Academy of Medicine, president of the Superior Consultative Committee of the Health Service in the room of M. Louis Barthou.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Executive Committee of this Fund was held on Monday, January 14th, at the offices of the *Lancet*, Sir Rickman Godlee presiding. Dr. Sprigge, the honorary secretary, reported that a letter signed by the Executive Committee, and including the letter from Mr. W. B. Poland, Director for Europe of the Commission for Relief in Belgium, had appeared in the medical and pharmaceutical journals in the last week of December (*BRITISH MEDICAL JOURNAL*, December 29th, p. 863). Arrangements were made to hold a meeting of the General Committee of the Fund at the house of the Royal Society of Medicine on January 31st at 3 p.m.; the propriety of subsequently calling a meeting of the whole constituency of the Fund was discussed, but a decision on this point was deferred until after the meeting of the General Committee. The importance of getting local committees to work, as was arranged when the appeal was first made, was pointed out by Dr. H. A. Des Vœux, the honorary treasurer, and Dr. C. O. Hawthorne.

Dr. Des Vœux made a financial statement which showed that there remained in the Fund now a total of only £1,096, while over a third of this sum had been received from the second appeal. The Committee felt that in these circumstances it would not be possible to send more than £400 to Belgium for the month of January, although they deeply regretted having in this manner to curtail the work which had been maintained without check for so long, and concerning whose great value to medical and pharmaceutical practitioners in Belgium they had received definite and pathetic proof.

SUBSCRIPTIONS.

The following subscriptions to the Fund have been received during the week ending Monday, January 14th:

	£	s.	d.		£	s.	d.
Dr. T. F. Keenan ...	1	0	0	Sir Rickman J. Godlee ..	34	8	0
Dr. N. J. McKie ...	1	1	0	Dr. A. S. Hedley ...	1	1	0
Mr. Alfred Wright ...	0	5	0	Dr. Allan ...	1	1	0
Dr. A. Gordon Watson ...	1	1	0	Dr. E. L. Bunting ...	2	2	0
Dr. Annie E. Clark ...	2	2	0	Dr. Percy Kidd ...	5	0	0
Captain H. H. Taylor ...	5	0	0	Dr. Dawson Williams ...	5	5	0
Dr. W. J. Dewar ...	2	2	0	Dr. Elsie M. Chubb ...	2	2	0
Dr. E. T. McDonnell ...	1	1	0	Dr. J. Quinton Bown ...	2	2	0
Sir Clifford Allbutt ...	5	0	0	A Friend ...	10	0	0
Dr. A. H. Peniston ...	1	1	0	Dr. S. Squire Sprigge ...	5	5	0
Dr. H. Simmons ...	2	2	0				

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

Obituary.

WILLIAM JULIUS MICKLE, M.D. TORONTO,
F.R.C.P. LOND.

WE regret to announce the death of Dr. Julius Mickle after a protracted illness. He died at Ottawa in November last at the house of his sister, Mrs. Bell, with whom he lived during the last few years of his life.

Dr. Mickle was a graduate of Toronto, where he took the degree of M.D. in 1867; he had a distinguished career as a student in Canada; he then came to England, studied at St. Thomas's Hospital, and took the diplomas of M.R.C.S. and L.S.A. in 1869. Later he became assistant physician at the Derby and Warwick Asylums, and it was here that he first recognized the importance of syphilis in the production of organic disease of the nervous system. In 1879 he became a Member of the Royal College of Physicians; afterwards he was appointed medical superintendent of Grove Hall Asylum, Bow, E.

In 1876-77 he published a paper in the *British and Foreign Medico-Chirurgical Review* entitled Syphilis and Insanity. Subsequently he published a number of papers on general paralysis of the insane, and in 1886 the second edition of his work *General Paralysis of the Insane* appeared. It is by this book that Dr. Mickle's name will be most remembered, for he was one of the first in this country to point out the close relation between the incidence of general paralysis and syphilis. Evidently his work

attracted considerable attention in the profession, for he was elected to the Fellowship of the Royal College of Physicians in 1887, and the following year he delivered the Goulstonian Lectures, the subject being "Insanity in Relation to Aortic and Cardiac Diseases." In 1895 a valuable article on syphilis of the nervous system was contributed by Dr. Mickle to *Brain*, and not long after he was elected president of the Neurological Society. He published many other papers bearing upon mental diseases, of which he had a wide experience. For many years he lectured on mental disease at University College and at the Middlesex Hospital.

Dr. Mickle was a careful and reliable observer and he did not fail, as happens with some specialists, to see the obvious. His long association with the Neurological Society (at the meetings of which he was a regular attendant) showed his bent, as an alienist physician, was to seek where possible a material cause of mental disorders. The present advance in our knowledge regarding syphilis as the sole and essential cause of general paralysis shows that Dr. Mickle was a pioneer in recognizing the association between syphilitic lesions of the aorta and general paralysis.

For a long time he took an active interest in the work of the British Medical Association. He was a member of the Parliamentary Bills Committee and the organizer and director of the work of its Lunacy Laws Subcommittee. He had a very extensive and accurate acquaintance with lunacy laws and administration, and his assistance in dealing with questions of this nature was always readily placed at the disposal of the Subcommittee and of this JOURNAL. He was secretary of the Section of Psychology at the annual meeting in Liverpool in 1883 and vice-president at Glasgow in 1888. He was president of the section at the annual meeting in London in 1895 and again at the meeting in Toronto in 1906, when he was given the Hon. LL.D. of his Alma Mater.

Dr. Mickle retired about ten years ago; his health failed during the last few years, and as he had no close ties in England the writer advised him to return to Canada a few years ago, where he remained with his relations until his decease.

F. W. MOTT.

THE death occurred on January 14th, at Coatbridge, of Dr. CHARLES O'NEILL, Nationalist M.P. for South Armagh since 1909. Dr. O'Neill was born in 1849. He received his medical education at Glasgow University, where he graduated M.B., C.M., in 1892. From 1897 to 1899 he was assistant professor of botany at St. Mungo's College, Glasgow. He was J.P. for the County of Lanarkshire, and was for some years the senior magistrate at Coatbridge. He was first returned as member for South Armagh at a by-election in November, 1909; he was re-elected unopposed in the following January, and held his seat at the next general election in December, 1910, thus being thrice elected for the same constituency within thirteen months.

COLONEL SIDNEY KEYWORTH RAY, Army Medical Staff (retired), died at West Kensington on January 2nd, aged 81. He took the diplomas of M.R.C.S. in 1858 and L.S.A. in 1859, and the F.R.C.S. Edin. in 1889. He entered the Army Medical Department as assistant surgeon on April 20th, 1859, became surgeon on April 20th, 1871, surgeon-major on March 1st, 1873, and retired as brigade surgeon on July 31st, 1891; but was promoted to colonel on October 18th, 1902, for services in England in connexion with the South African war. He served in the Egyptian war of 1882 and received the medal with a clasp and the Khedive's bronze star.

SURGEON-LIEUT.-COLONEL WILLIAM BENJAMIN CHATTERTON DEBBLE, R.A.M.C. (ret.), died at a nursing home at Ryde, Isle of Wight, on December 28th, 1917, aged 59. He was educated at St. Bartholomew's Hospital, took the diplomas of M.R.C.S. and L.R.C.P. Edin. in 1881, and entered the army as surgeon on February 3rd, 1883, becoming surgeon-lieut.-colonel on July 23rd, 1903, and retiring on September 27th, 1911. Most of his service was passed in the Household Brigade, as medical officer of the 1st Life Guards.

Universities and Colleges.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on December 19th, 1917. Sir Seymour Sharkey, M.D., F.R.C.P., has been appointed chairman of the Graham Legacy Committee for the remainder of the year 1917-18; Dr. A. E. Boycott, F.R.S., has been re-appointed Director of the Laboratory, and Dr. C. Bolton acting Director during the absence of Dr. Boycott on military duty.

University Medal.—The University medal at the M.B., B.S. examination in October last has been awarded to A. E. P. Parker, of Westminster Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a quarterly council held on January 10th, when Colonel Charters Symonds was in the chair, the thanks of the Council were given to Colonel C. E. Shepherd for his gift to the Museum of a collection of otoliths of bony fishes and other gifts during the last eleven years, to Sir Robert Jones for presenting to the library a collection of the published works of the late Mr. H. O. Thomas, and to Sir Rickman Godlee for a copy of his biography of Lord Lister.

Surgeon-General Sir Anthony A. Bowlby, K.C.M.G., will deliver the Hunterian Oration in 1919.

The names of two members, previously erased from the *Medical Register*, were removed from the College list.

Medical News.

It is proposed to make venereal diseases notifiable in Philadelphia.

CAPTAIN HENRY L. MARTYN, M.B., F.R.C.S., R.A.M.C., has been appointed one of the Surgeons-Apothecary to His Majesty's household at Windsor.

THE Carmarthen Town Council has decided to confer the freedom of the borough upon Captain Ernest Emrys Isaac, R.A.M.C., who has been awarded the Military Cross with a bar.

DR. CECIL P. LANKESTER (Guildford), secretary of the Surrey Branch of the British Medical Association, has been appointed an honorary associate of the Order of St. John of Jerusalem in England.

A PERUVIAN Medical Commission is making a tour of inspection of the schools of medicine in the United States with the object of collecting information to be used for the reorganization of the medical schools of Peru in accordance with American standards.

A COURSE of advanced lectures on infant care for nurses, health visitors, teachers, infant welfare workers, and mothers has been arranged by the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, and particulars can be obtained on application to the secretary, 4, Tavistock Square, London, W.C.1. The lectures, which will be given at the house of the Royal Society of Medicine, 1, Wimpole Street, begin on January 28th, at 5.30 p.m.

THE Local Government Board has issued a circular drawing attention to the revised arrangements for the provision of treatment for men discharged from the army and navy on account of tuberculosis. Hitherto accommodation has been found by the Insurance Commissioners, or by Insurance Committees, for insured men needing residential treatment; while in the case of uninsured men the Local Government Board has arranged for the provision of residential treatment for such as were not in the position to obtain this at their own expense. Under the provisions of the National Insurance Amending Act, 1917, the Insurance Commissioners, after consultation with the Ministry of Pensions and the Local Government Board, have made regulations extending sanatorium benefit to all invalided uninsured sailors and soldiers whose income from all sources does not exceed £160 a year. Uninsured officers, nurses, non-commissioned officers and men whose income exceeds that sum will be dealt with by the Ministry of Pensions. While county and county borough councils are now relieved of the duty of providing directly for the treatment of uninsured army and navy cases, it is anticipated that Insurance Committees generally will desire to arrange with the Councils of their areas for the provision of residential treatment for discharged sailors and soldiers suffering from tuberculosis. Steps are being taken to provide additional accommodation at convenient centres in different parts of the country. A further circular will be issued on the subject of home-visiting and after-care.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES.

RATIONS IN SANATORIUMS.

THE medical superintendent of a sanatorium for consumptives, finding it impossible adequately to feed patients suffering from tuberculosis on the proposed rations, asks whether any special provision is made in respect of sanatoriums.

* The rations are voluntary, and there is not, we believe, any intention that patients should be strictly confined to them if that would mean that their successful treatment would be endangered. The special position of sanatoriums for consumption will, we understand, be brought before the Rationing Committee at an early date.

FINGER CRACKS.

A CORRESPONDENT asks advice as to the treatment of deep cracks in the skin of the ends of the fingers, which recur each winter and cause some disability.

* The hard edges of really deep cracks should first be ground away with pumice stone, sandpaper, or a suitable file; if this be not done the dried hard epidermis prevents the more elastic layers underneath having free play, with the result that the hard edges cause the cracks to become deeper and therefore more painful. For immediate relief, when rough or dirty work has to be done, strips of Mead's plaster should be used. To attempt a permanent cure a stiff ointment is probably the best application. It should be applied at night, and gloves or finger-stalls worn. The ointment should be renewed as often as necessary during the day to keep the cracks well greased. Some years ago Dr. Alfred Eddowes suggested the following ointment, which has proved very useful: White beeswax 300 parts, gum arabic of good quality 350 parts, boiled in 300 parts of water; to this 50 parts of glycerin and 100 of water are added. The ointment should be quite stiff; for this purpose a little lanoline may be added and the proportion of water reduced.

TERRITORIAL DECORATION.

A CORRESPONDENT on active service with the British Expeditionary Force, having noticed the recent grant of Territorial Decorations to several medical officers, asks as to the conditions at present in force.

* We find that the grant is governed by the following paragraph of Army Council Instructions, 1916 (p. 48):

782. Recommendations for the award of the Territorial Decoration for officers and . . . of the T.F. when serving with an expeditionary force will be held in abeyance during the war. In the case of officers . . . killed in action or who die of wounds, etc., the necessary recommendations will continue to be forwarded to the War Office in order that the decoration or medal may be issued to the next of kin.—68 Gen. No. 2731 (T.F.).

EXCESS PROFITS DUTY.

J. W. inquires as to the position of a medical man who conducts a private hospital.

* So much depends on the exact nature of the services for which payment is received that a definite answer cannot be given without more knowledge of the facts; it would depend on the consideration of evidence tending to show whether the profits arise from the successful organization and working of the hospital or from the professional exercise of our correspondent's personal skill. In view of the reference in the Acts to the criterion of the employment of capital we think that *prima facie* a hospital would be on a footing similar to that of a nursing home. We assume that the hospital in question is not merely ancillary to "J. W.'s" practice, in which case he would have stronger grounds for objecting to an assessment. The percentage charge has varied. For the first period of twelve months ending after August 4th, 1914, the rate is 50 per cent., then 60 per cent. to January 1st, 1917, when it becomes 80 per cent.

INCOME TAX.

"A MEMBER" inquires as to allowance for fire insurance and agent's charges from the assessment of rents on properties.

* One-sixth is allowed from the gross rental value of the properties when they are assessed, and this has been held to cover the allowances claimed. But if the property concerned consists of lands or houses not exceeding £12 in gross rental value, a repayment can be claimed reducing the amount of tax to the sum due if the total expense of maintenance had been calculated on the average of the five previous years, and deducted from the rents. If the property in question consists of houses exceeding £12 in rental value our correspondent has no claim; otherwise he might request the local surveyor of taxes to send him a form of claim under Section 69 of the Finance (1909-10) Act, 1910, giving further information on the point.

LETTERS, NOTES, ETC.

ON WRITING WITH THE LEFT HAND.

DR. HEYWOOD SMITH (Dove) writes: Following Sir Frederick Treves's interesting review of Professor D'Urso's book (p. 16) I write to ask whether it would not be easier for some men to write backwards (mirror writing) with the left hand. In our ordinary writing with the right hand the majority of letters are formed by curves from right to left, and if we try and write backwards (that is, from right to left with the right hand it takes some effort, and the result is rather that of a child's writing; whereas if we write backwards with the left hand the curves are from left to right. If we write simultaneously with both hands, with the right as ordinarily and with the left backwards, this will be quite evident. Again, it is a curious fact, depending probably on unconscious brain work, that the backward writing by the left hand shows all the individual characteristics of the right hand writing, and can therefore be recognized as the writing of the individual. The left hand writing can be easily read in a mirror, or, if on thin paper, can be read by holding the paper up to the light.

* If any one will make the experiment he will find that it is comparatively easy to write mirrorwise with the left hand. Sir James Barr has pointed out to us that a very practical way of utilizing mirror writing is to let the man write on thin paper, with under it an ordinary piece of type-writing carbon paper face upwards. When the top page is turned over, the writing, though done from right to left, appears in the correct way, from left to right. A curious fact is that if with the eyes shut a pencil is taken in either hand and curves made simultaneously, they will be found to be nearly symmetrical.

HONOURS AND REWARDS.

R.A.M.C. writes: I have been reading in the paper the curiously conglomerate list of names of those people who are included in the Order of the British Empire. I have been carrying on, doing my miniature bit, in a public service for three years, but I hope ere long to be enabled, at the termination of this great war, to return to my home and to my diminished practice, and the honours which I anticipate will be bestowed upon me, and on other general practitioners, will be the knowledge that in the unprinted list, in which will be included the comparatively few of those who have served their country, my name will appear.

It is apparent to me that those desirous of public decoration should have stayed in England, to have enjoyed their own home comforts, and to have posed before the grateful authorities as patriots who have not forsaken their native soil. For myself, contrary to the example set by a personal friend of mine, who has hitherto given his war service in the intervals of professional private practice, and has received so far two decorations from his thoughtful country, and has not deserted the London atmosphere, I find as one who has expended his personal energies at a very mature but healthy age in travelling more than 100,000 miles with our sick and wounded in various parts of the war zone, that the recognition of my services remains, and will doubtless remain, wrapped up in the bosom of my own family.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

Observations

ON

WAR SURGERY OF THE CHEST.

BY

CAPTAIN A. L. LOCKWOOD, M.C., R.A.M.C.,

AND

CAPTAIN J. A. NIXON, R.A.M.C.(T.F.).

PART I.

THE surgery of gunshot wounds of the chest has attracted considerable attention during the past few months, and there has been a general trend in the direction of more active surgical measures. Any discussion upon war surgery of the chest must nowadays include abdomino-thoracic as well as thoracic wounds. It is no longer possible to separate for treatment or discussion "pure chest wounds."

At the outset of our work we felt that one chief problem to be faced was the recognition of those cases which recover without operation as distinguished from those which, unless operated upon, are inevitably fatal. Speaking broadly, the cases upon which we now perform a complete intrathoracic operation, and for which we advise this operation, belong solely to the latter group.

We feel compelled to add that in our opinion the complete intrathoracic operation stands at present in some danger of being performed upon cases in which it is neither necessary nor justifiable. We do not advocate it for haemothorax *per se*. We are aware that our conclusions and our methods do not accord with those in vogue elsewhere or advocated in articles recently published, but we are convinced that the procedures which we shall describe, especially the early resuscitatory methods, the diagnostic measures, the exact localization of missiles, the operative technique, and the post-operative treatment, are essential and indispensable.

From our own experience, and from our intimate association with Duval, we believe that unless surgeons have kept their chest cases under their own observation until convalescence is complete it is impossible for them to form correct conclusions as to the value and ultimate results of their treatment.

During the whole of the Somme offensive from July, 1916, it was found possible to retain all serious chest cases in the unit even until thoroughly convalescent. This was due to the fact that Sir Wilmot Herringham underlook the care of these cases at a time when the regular officers of the unit were fully employed in dealing with what were then considered more urgent cases. By degrees the importance of not evacuating severe chest cases was appreciated. Since August, 1917,* all chest cases, whether serious or slight, have been retained in the casualty clearing station until they were up and about and able to do light duty. Apparently the opportunities for holding cases for such a long time have not existed in any other British front unit.

In forming conclusions as to treatment and mortality figures it must be borne in mind that chest wounds, in common with all other wounds, show wide variations in their course, dependent upon the soil of the battle ground, the nature of the weapons used (rifle, shell, or bomb, etc.), the use of gas, the weather conditions, and the facilities for rapid evacuation.

Up to the middle of 1916 we had treated wounds of the chest for the most part expectantly. We had not even considered it necessary to excise the parietal wound unless badly infected, although excision of all other wounds was regarded as of paramount importance.

While the treatment of wounds involving the chest alone consisted in the early stages in absolute rest and non-interference, and later operations were dictated by infection of the thoracic cavity, nevertheless, injuries extending to the abdomen and involving the diaphragm were recognized by us as demanding immediate operation, and not being "necessarily fatal."

As early as the middle of July, 1916, it was realized that practically all wounds of the diaphragm left unrepaired proved fatal. From that period all cases diagnosed or suspected of having a diaphragmatic lesion were operated upon. Repair of the diaphragm was found to be of

greater urgency than the repair of any hollow or solid viscus in the abdomen.

But repair of the diaphragm was not always sufficient. In some cases there existed a serious lesion of the thorax or its contents. At first we did not appreciate that in such cases the operation should extend further, and that for complete success repair of the intrathoracic lesion must be included.

The stages by which we gradually evolved our treatment of thoracic and abdomino-thoracic injuries were briefly as follows:

1. The parietal wound was excised, the comminuted fragments of rib removed, and the pleura, if possible, closed. No attempt was made to clear out the haemothorax, or to follow the missile into the chest. Repair of the thoracic contents was not embarked upon.

2. In July, 1916, repair of the diaphragm became a routine procedure by the abdominal route.

3. Extensive injuries to the bony skeleton of the thorax were seen to be almost invariably fatal. The principal cause of death was not sepsis. The patients did not recover from the shock and exhaustion of gross bony lesions until we began to remove all comminuted bone and sharp spicules. From this time it became an established rule to operate on the parietes on all "stove-in" chests.

4. An important advance was made when a case was recognized in which the diaphragm was injured by a purely thoracic wound. A successful operation was performed by the thoracic route instead of, as previously, by the abdominal. Thenceforward we adopted the practice of dealing with thoracic injuries of the diaphragm through the thoracic wound.

5. Up to the end of 1916 open (sucking) wounds of the chest—traumatopnoea—had shown a mortality of almost 100 per cent. Various methods of plugging the hole in the chest wall were found to postpone, but not to avert, the fatal result. At this time we realized that it was practicable to excise the parietal wound, clear out completely the haemothorax, and close the opening in the chest wall.

EVACUATION AND EARLY HANDLING.

At the advanced dressing station, apart from cases which die before they can be moved, certain cases are received which are not fit to travel until they have rallied to some extent. Into this category come cases of traumatopnoea. This type of wound requires to be carefully cleaned without an anaesthetic and the skin sutured with silkworm gut through a plug of gauze so that there is no leakage of air. The improvement in the patient's condition is often marvellous within an hour or two of being sutured. The mental distress which accompanies traumatopnoea is at once relieved. The lung often expands and the respirations become deeper, easier, and more regular. Cases should travel direct from the advanced dressing station to the surgical unit dealing with chest wounds.

We believe that chest cases requiring early operative treatment require it as urgently and as promptly as abdominal cases.

RESUSCITATION.

Immediately on admission to the casualty clearing station these cases are dressed in clean pyjamas, laid between warmed blankets in a heater in the position most comfortable to the individual case, but, if possible, with the injured side dependent. Continuous rectal administration of sod. bicarb. and glucose (5 per cent. each in water) is started. Intravenous sod. bicarb. (2 per cent.) is given if required, and in a large percentage of severe cases immediate blood transfusion (600 to 800 c.cm.) is administered with the minimum of disturbance to the patient, preferably by the new "No. 17" or the Kington Browne tube.

Hot drinks by the mouth, especially cocoa, are given freely, but no stimulants whatever. As Crile has insisted, sleep is the great restorative, and should be procured by every means and device, such as a plug of cotton wool in the ears, subdued lights, perfectly quiet surroundings, and omnopon or morphine, the former for choice. Urgent dyspnoea from haemothorax or pneumothorax should be relieved before operation by aspirating. If fresh haemorrhage is suspected, the aspiration should be partial and combined with oxygen replacement.

DIAGNOSIS.

As soon as his condition permits, the patient should be thoroughly examined by the surgeon and the physician

* Throughout this paper the term A Group refers to cases prior to August, 1917, and the term Z Group refers to cases after August, 1917.

together with the *x* rays, at the patient's bedside, in order to decide whether immediate operation is required.

SURGICAL MEASURES.

The surgical measures which these cases appear to justify should not be attempted unless:

- (a) Active resuscitation can be carried out immediately after admission.
- (b) The services of an expert radiographer are at all times available.
- (c) The physical signs can be carefully studied and judiciously interpreted.
- (d) The most perfect asepsis can be secured at the operation.

Given these conditions, we are guided by the following general rules for operation:

1. Operate as soon as the patient's condition allows. (This is much earlier with local than with general anaesthesia.)
2. Operate at a place where early evacuation will not be necessary.
3. Operate in all cases where injury of the diaphragm is suspected.
4. Operate on all cases with open pneumothorax (traumatopnoea).
5. Operate on all badly "stove-in" chests, where the pleura is lacerated, even though there is no external wound.
6. Operate on all cases where a large missile has traversed the pleural cavity, whether lodged in
 - (a) The chest wall,
 - (b) The pleural cavity,
 - (c) The lung,
 - (d) The mediastinum, or
 - (e) The pericardium.
7. Operate on all very acutely infected cases, even although the missile is not retained.

Accurate localization of the missile and correct interpretation of the *x*-ray plates are essential and of the greatest value in diagnosis. Movements of the thoracic contents and the diaphragm, as well as the position and degree of movement of the missile, can only be determined with the screen.

Full-size stereoscopic plates showing both sides of the chest and the diaphragm should be taken.

The *x* rays show the approximate amount of haemothorax, the presence of pneumothorax, haematoma of the lung substance, the degree of collapse of the lungs, the position of the diaphragm, and the position of the heart and mediastinum and the comminution of the ribs. Repeated *x*-ray examination of the chest is essential during the progress of the case. A sectional atlas of the Symington type is found of the greatest assistance in determining the relative position of the missile and the structures probably traversed. An aluminium-topped combined operating and *x*-ray table of the type of the Bonnette Eclipse du Dr. Dessane is of the greatest service.

CLINICAL SYMPTOMS AND SIGNS.

The physical examination of the patient should always be limited in the first instance to ascertaining whether an immediate operation is advisable or possible.

If the patient has any of the conditions enumerated above as indications for operation, and he can stand one hour's surgical interference, a meticulous examination of all the physical signs which the chest may present is unnecessary, and will not influence the decision to operate. But it should be borne in mind that if the missile has traversed the mediastinum and penetrated both sides of the chest early operative treatment should never be undertaken.

The presence of considerable surgical emphysema obliterates or distorts every other physical sign except the position of the heart. When considerable surgical emphysema has developed in the chest wall there is, as a rule, pneumothorax underlying it. Marked displacement of the heart may indicate that the heart has been pushed out of position by fluid or air. In disturbances of the respiratory mechanism due to injuries of the diaphragm, displacement of the heart to the injured side has been found. The signs described as those of "contralateral collapse" have been recognized by us in very few cases.

Early operation on cases showing the signs and symptoms of bronchopneumonia on the uninjured side must not be lightly undertaken, but if undertaken local anaesthesia alone must be used.

Physical signs suggesting involvement of the pericardium or heart do not constitute a contraindication to operation; they are, moreover, most fallacious.

The churning sound usually associated with haemopneumopericardium has been met with where this condition did not exist. A tumultuous and irregular heart-beat has been seen when the pericardium had not been even penetrated. This phenomenon undoubtedly results when the heart has been hit by a large missile which has rebounded, and—with the *x* rays—is seen to be lying at some distance from the heart. Autopsy has revealed two such cases, with severe bruising of the heart. The regularity of the heart-beat is disturbed when the position of a missile is such that, with each beat, the posterior aspect of the heart touches the missile. A cardiac impulse visible with the *x* rays is frequently seen in a missile lying some little distance outside the pericardium and not in actual contact with the heart.

Respiratory distress does not always accompany even the largest effusions. The degree of movement in a chest is not always proportionate to the intrathoracic injury. Immobility may be very complete without intrathoracic lesion. There is a condition met with when the chest has been hit without production of haemothorax or pneumothorax in which the injured side remains retracted, resonant, and silent, but with normal vocal fremitus and normal *x*-ray appearances. This condition persists for one or two days and recovers completely.

Tactile vocal fremitus is not always diminished, and is occasionally increased over haemothorax. The level of dullness does not indicate the size of a haemothorax. Bronchial breathing is not uncommon over a haemothorax. Haemothorax occurs although the pleura has not been penetrated.

Amphoric breathing is frequently heard over pneumothorax. The coin sound is sometimes absent even in large pneumothorax. The heart has been found in normal position in total pneumothorax of the left side. Physical signs alone will not distinguish gas from air. Pneumothorax does not always develop rapidly after the injury; it is sometimes a late and gradual occurrence.

Signs of increasing effusion after twenty-four to thirty-six hours are scarcely ever due to active haemorrhage, and recurrent haemorrhage has been seen by us only in five cases.

It has been a puzzle to us why haemothorax so constantly develops in chest injuries. Seldom have we found the intercostal artery to be ruptured, or, at any rate, still bleeding; rarely, if ever, have we seen anything but the slightest oozing from lacerated lung except when it is held up by adhesions. At operation, even in lungs only partially collapsed, excision of the track or bed of the missile is accompanied by remarkably little haemorrhage.

The portion of the paper dealing with operation and post-operative treatment is postponed for lack of space in this issue, and will appear as Part II next week. The remainder of Part I consists of statistical tables and case summaries.]

STATISTICAL TABLES AND CASE SUMMARIES.

I.—Analysis of Admissions.

Z GROUP.

(August to November, 1917.)

Total cases, 158.

Operated, 82.*				Non-operated, 55.†	
Thoracic, 53.		Abdomino-thoracic, 29		Lived, 55.	Died, 31.
Lived, 40. (Table V.)	Died, 13.	Lived, 18. (Table IV.)	Died, 11.	Thoracic, 20.	Abdomino-thoracic, 11.

* The figures in thoracic cases show a high percentage of recoveries in cases that previously showed a mortality of nearly 100 per cent.

† A high proportion of non-operated cases were brought in dead (9), or died within a few hours of admission (21). In the cases that lived longer than a day or two the serious nature of their injuries will be seen in the analysis of fatal cases (Table VI).

II.—Comparative Number of Abdomino-thoracic Operations Performed before and after August, 1915.

A GROUP.

(Before August, 1915.)

Total chest cases admitted	1,254
Abdomino-thoracic operations (Table III)	60
Lived	32
Died	28

Z GROUP.

(After August, 1915.)

Total chest cases admitted	168
Abdomino-thoracic operations	29
Lived (Table IV)	18
Died (Table VI)	11

* A Group: No percentage mortality is given in this group, which consists of 1,254 admissions. This is partly due to the difficulty of tracing cases which were evacuated early. The figures for one month illustrate the small value of comparing records of percentage mortality from chest wounds. In September, 1915, 203 cases were admitted to a special chest ward; of these only 16 died. The explanation of this low death-rate—in a group which might be represented as the total of chest wounds admitted—lies in the fact that abdomino-thoracic injuries were taken into surgical wards and classified separately.

V.—Analysis of Thoracic Cases Operated on (Recoveries only).*

Z GROUP.

Cases 1 to 10.—Each of these patients was admitted with a large parietal wound of the chest with haemothorax. In all cases the wound was excised, without opening the chest. After-treatment consisted of aspiration. There were no complications. Case 3 was evacuated on the third day, and Case 6 on the fifth; the other cases were out of bed on the 20th, 12th, 13th, 20th, 18th, 8th, 11th, and 11th days respectively.

Case 11.—Large parietal wound of chest with haemothorax: multiple wounds. At operation the chest and other wounds were excised (chest not opened), and the right arm was amputated. Subsequently the patient developed bronchopneumonia (right and left). He was evacuated on the seventeenth day.

Case 12.—Large parietal wound; two ribs comminuted; haemothorax. Wound excised; ribs trimmed; chest not opened. Aspirated. Patient got up on the twentieth day.

Case 13.—Large parietal wound; two ribs comminuted; haemothorax; multiple wounds. Chest and other wounds excised; ribs trimmed; chest not opened. Aspirated; later bronchopneumonia developed. Patient got up on the twenty-eighth day.

Case 14.—Large parietal wound; one rib comminuted for four inches. Chest wound excised; rib trimmed; chest not opened. Later the chest was aspirated, and the patient was out of bed on the twentieth day.

Case 15.—Large parietal wound admitting two fingers; two ribs comminuted. Chest wound excised; ribs trimmed; chest not opened. Aspirated. Patient got up on the twentieth day.

Cases 16 and 17.—Large parietal wound; traumatopnoea; gutter wound; missile not traversing pleural cavity; no gross comminution of ribs. Parietal wound excised; opening in chest closed without exploration. Subsequently both cases were aspirated. Case 16 was up on the twentieth day. Case 17 developed gas gangrene of the chest wall, but was out of bed on the fifty-fifth day.

Case 18.—Traumatopnoea. Complete operation. Later, chest aspirated. Got up on the thirty-fifth day.

Case 19.—Traumatopnoea. Complete operation, except left open at end of operation. Extensive gas gangrene of chest wall and lung at time of operation. Evacuated on the eighty-sixth day.

Cases 20 to 24.—Traumatopnoea with laceration of lung. Complete operation. Aspirated. Case 20 was up on the

(Continued on p. 109.)

* Haemothorax or haemopneumothorax was present in every case. Fatal cases (49 in number) are shown in the general table of deaths in Z Group (Table VI).

V.—Analysis of Thoracic Cases Operated on (Recoveries only).— (Continued.)

twentieth day; Case 21 on the nineteenth; Case 22 on the fifteenth; Case 23 on the thirtieth; and Case 24 on the twenty-first.

Case 25.—Traumatopnoea with hole in lung admitting two fingers. Complete operation. Aspirated. Got up on the thirty-fifth day.

Case 26.—Traumatopnoea with hole in lung admitting two fingers. Complete operation. Aspirated, but leaked pus (staphylococcus) from localized empyema. Was out of bed on the sixty-fourth day.

Case 27.—Traumatopnoea with missile lodged in mediastinum. Complete operation; missile removed from mediastinum. Aspirated. Got up on the fiftieth day.

Case 28.—Traumatopnoea (hole into chest admitting two fingers) and laceration of lung. Complete operation. Aspirated; leaked pus (staphylococcus) from localized empyema; closed completely and spontaneously. Patient was out of bed on the ninety-sixth day.

Case 29.—Traumatopnoea (admitting three fingers); laceration of lung, pericardium perforated. Complete operation; small missile not removed. Aspirated. Got up on the twentieth day.

Case 30.—Penetration of chest and mediastinum; laceration of lung. Complete operation; missile removed from mediastinum. Aspirated; leaked pus (staphylococcus) from mediastinum; closed completely and spontaneously. Got up on the twenty-eighth day.

Case 31.—Penetration of chest; laceration of lung; multiple wounds. Complete operation; multiple wounds excised. Aspirated. Got up on the forty-first day.

Case 32.—Penetration of chest; multiple wounds. Complete operation; multiple wounds excised; amputation of left arm. Aspirated. Evacuated on the thirty-fifth day.

Cases 33 to 36.—Penetration of chest; laceration of lung. Complete operation; missile removed, except in Case 35. Aspirated. Case 33 got up on the fortieth day; Case 34 on the forty-fifth; and Case 35 on the sixty-fifth. Case 35 was evacuated on the twenty-first day.

Case 37.—Penetration of chest (through-and-through); laceration of lung. Complete operation on the ninth day, because of *B. perfringens* infection. Infected haemothorax (*B. perfringens* and streptococcus); operation late. Developed empyema after operation; aspirated four times (cultures unchanged). Recovery without drainage. Was out of bed on the fortieth day.

Case 38.—Penetration of right and left chest; mediastinum traversed; missile lodged in heart; right haemothorax. Aspiration of right chest only at first. Later, complete operation on left side; missile not removed. Patient got up on the sixty-fifth day.

Case 39.—Penetration of right and left chest; one large parietal wound; double haemothorax. Complete operation on side of parietal wound. Aspirated. Got up on the forty-fifth day.

Case 40.—Crushed chest, no external wound; four ribs fractured on the left side, and two on the right; left haemothorax. Complete operation, left side. Aspirated; empyema developed. Patient was out of bed on the seventieth day.

Note.—In the Z group the proportion of bomb and shell wounds was unusually high; only two cases were wounded by rifle bullets and two by shrapnel ball. The severity of the group, considered as a whole, was exceptional.

As regards the operations performed, none were left open at operation, except one with extensive gas gangrene of the entire left lung and chest wall. The case was considered absolutely hopeless, but made a good recovery, and has been evacuated with a large opening (2½ in. in diameter) in the chest wall not yet healed.

No case was reopened, but five leaked pus from their incisions—as a rule, at the most dependent part. We believe this was due to localized collection of pus in the pleural cavity adjacent to the incisions, because the lungs as a whole were well expanded.

Spontaneous closure of the sinuses took place without interference with the wound or sinus, except in one case still discharging a little pus at the time of evacuation, and one case—with gas gangrene of chest wall and lung—which reopened completely and died twenty days after operation.

The improvement in results of the abdomino-thoracic operations we believe to be due to the more complete thoracic operation which is being done as part of the combined operation.

All cases in the Z group were anaesthetized with novocain and gas and oxygen (if required), except two (multiple wounds), who had not ether.

In every fatal case complete autopsy was performed, except five in which the lesions of the chest and the accompanying multiple wounds were so gross that there remained little more to expose.

VII.—Empyema occurring in Non-operated Cases. (Five Cases.)

Case 1.—Penetration of chest, through-and-through (rifle bullet). Patient moribund on admission. Haemopneumothorax aspirated repeatedly; condition scarcely improved. Later empyema developed (streptococcus and staphylococcus). Treated by repeated aspirations. Condition remained very grave. Resection and drainage on the thirty-ninth day. Evacuated (not convalescent) on the forty-seventh day. He reached England and had got out of bed, January 9th, 1918.

Case 2.—Penetration of chest, right and left; fractured ribs both sides, comminuted on right; probable injury of liver (developed jaundice); right haemothorax. Moribund on admission. Developed double bronchopneumonia. The case appeared hopeless and operation impossible, but recovered with late development of empyema (right); cultures sterile! Resection and drainage on twentieth day. Evacuated on the twenty-seventh day, convalescent but still draining.

Case 3.—Small parietal wound of chest; multiple wounds; chest not penetrated. Developed pneumonia with empyema (pneumococcus) on side of parietal wound. Aspirated, and eventually drained without resection of rib. Closed rapidly after drainage. Evacuated, convalescent, on the forty-third day.

Case 4.—Penetration of chest; left haemothorax with active haemorrhage on aspiration. Aspiration repeated with oxygen replacement. Moribund on admission. Developed empyema (staphylococcus); repeated aspirations (28½ oz. withdrawn in all). Developed acute parenchymatous nephritis. Empyema cleared without resection; nephritis improved greatly; trace of albumin remained. Evacuated, convalescent, on the eighty-third day.

Case 5.—Penetration of chest, through-and-through; small haemothorax, right. Haemothorax aspirated. Developed double bronchopneumonia and empyema on side of haemothorax. Aspirated; not resected. Died on the twenty-sixth day.

THE TREATMENT OF SEPTIC HAEMOTHORAX AND EMPYEMA.

By CAPTAIN J. CAMPBELL, R.A.M.C.(S.R.).

QUITE a number of cases of septic haemothorax in the early stage can be successfully treated by resection of a portion of rib and careful removal of all fluid and clot, followed by washing out and complete closure of the pleural cavity. On the other hand, a severely septic haemothorax does not yield to such treatment, and frequently leads to death of the patient (50 per cent. of cases) either from septicaemia or general toxic absorption. Short of this unfortunate result, drainage as usually carried out by the insertion of a large tube in the pleural cavity is followed by long severe pyrexia and exhausting suppuration.

The excellent results obtained elsewhere by the Carrel-Dakin method suggested that considerable advantage might be obtained from its use in some modified form in these cases also. Accordingly, I made several attempts to use it in different ways, but found that the most convenient and beneficial method is as follows:

The patient is *x* rayed, and any foreign body carefully localized. Under a general anaesthetic the wound is explored, the fractured portions of rib resected, and the wound sewn up if its condition allows.

The pleural cavity is then drained in the usual fashion, resecting about three and a half inches of rib as far forwards and as low as possible—that is, usually the eighth rib in the mid or anterior axillary line. Through this opening the cavity is explored, and an easily accessible foreign body and fragments of loose bone lying in the cavity or on the surface of the lung removed. Blood clot and fibrin are swabbed out as far as possible, and any septa forming loculi broken down. The cavity is next washed out with a warm mixture of hydrogen peroxide and eusol, or Dakin's solution. A rubber tube of a quarter of an inch internal diameter, with a large lateral opening a quarter of an inch from one extremity is then inserted, so that this end lies in the most dependent part of the pleural cavity when the patient is lying on the normal side—that is, in the costo-vertebral recess behind the pericardium. Finally, the wound is loosely sewn up, but no attempt is made to effect an airtight closure round the tube.

When the patient has recovered from the operation, the size of the cavity is estimated by filling it carefully (but usually incompletely) with warmed Dakin's solution, and then emptying it. After this the cavity is filled through the

tube every four hours to about one-third of its capacity or less with Dakin's solution. At the end of two hours another long tube is attached to the tube in the chest and the fluid siphoned out, the patient meanwhile lying on the sound side with the chest opening uppermost, or as nearly so as possible. The patient is told to pant or cough slightly at frequent intervals as long as the fluid remains in the chest, and by this means splash the fluid about inside the cavity, and so bathe with it the entire infected surface and any recesses that may exist.

In this way the pleural cavity contains for two hours a large quantity of sodium hypochlorite solution and is more or less empty for a like time. During the former period the patient lies rigidly on the sound side, without any raising of the shoulders, to prevent escape of the fluid and consequent flooding of the bed; during the latter he is free to lie as he chooses. Thus the patient gets a reasonable amount of rest and comfort and is saved the exhaustion associated with the maintenance of one constant position. In addition, once daily, the tube is removed, sterilized, and replaced, and the cavity washed out as in the usual treatment for empyema. To overcome the disadvantage of injecting cold fluid into the chest, I have found that it is better to make the Dakin's solution of double strength and, prior to filling, to dilute it with an equal quantity of warm sterile water.

If the original wound and site of fracture lie sufficiently far forwards, advantage is taken of this site for the insertion of the tube.

Sometimes difficulty is met with in siphoning out the fluid; this may be due either to the tube that is connected to the tube in the chest not being first filled with liquid or else to air being unable to enter the pleural cavity; in the latter case, it is well to slip an open-ended Carrel tube into the chest alongside the first. When this is done I use the smaller tube for filling up the pleura, as then the liquid cannot be injected too quickly.

When treatment is carried out in this way, it is found that pus formation and offensive odour largely disappear at the end of thirty-six hours and are absent at the end of three to four days; the patient's tongue becomes clean and moist almost at once; delirium and emaciation, so frequently seen in these cases, are absent, and the temperature and pulse rates fall much more rapidly than usual; indeed when looking at them, it is hard to distinguish these cases from those that are not infected.

If pus continues to form under this method of treatment, it appears to be due to one or more of the following causes:

1. The Dakin's solution is not of proper strength or is used in insufficient quantity.
2. The cavity is not regularly filled and emptied.
3. A loculated cavity exists which the fluid does not reach.
4. A foreign body or loose bone fragments still remain in the pleural cavity.
5. Sloughing or abscess formation is taking place in the lung substance.

After using this method of treatment on a number of cases I have found that it is superior to other methods of treatment that I have tried. The benefit derived from it can easily be demonstrated by the rapid diminution of the number of organisms per field of the microscope in films made from the surface of the pleura. By this method, too, it is comparatively easy to raise the pleural cavity to "suture standard" and sew up the wound at an early date, with the result that lung expansion becomes more perfect and pleural thickening is largely avoided. I think another great advantage is that cross infection of the empyema cavity from without is avoided.

It is only recently that vitiligo, or leucoderma, has been associated with syphilis. E. M. Auer (*Amer. Journ. Med. Sci.*, Phila., 1917, vol. cliv, pp. 592-596) gives about a dozen references from literature to this subject, and quotes Zelenev's analysis of 52 cases of leucoderma with the conclusion that, etiologically, they fall into two groups—tuberculous and syphilitic. Auer also reports four cases of leucoderma in patients with late syphilitic lesions of the central nervous system, and draws attention to the early appearance of leucoderma as compared with the other symptoms: he points out also that the symmetrical and segmental distribution of the areas of leucoderma suggests a lesion of the central rather than of the peripheral nervous system.

THE ENDOTOXIN OF THE MENINGOCOCCUS

A METHOD OF EXTRACTING IT FOR THE PURPOSE OF
STANDARDIZING ANTIMENINGOCOCCUS SERUM.

BY

M. H. GORDON, C.M.G., M.D.,

TEMPORARY HONORARY LIEUT.-COLONEL R.A.M.C.
(From the Central C.S.F. Laboratory, London.)

Few who have studied acute cases of cerebro-spinal fever during an outbreak can fail to be impressed by the potency of the toxin of the meningococcus, and if the observer is a bacteriologist he may be struck also by the relative infrequency with which this micro-organism is to be cultivated from the blood of the patients. Although the meninges are one of the chief sites of infection, a further feature of the disease that calls for notice is the relatively large number of pus cells that it may be necessary to search in film preparations of the cerebro-spinal fluid before one is found that contains meningococci. While there are occasional and striking instances in which the meningococcus is detected in large numbers in the cerebro-spinal system, or in the blood, in many cases of cerebro-spinal fever actual proliferation of the meningococcus in the tissues of the patient appears to be limited. Nor is this relatively restricted proliferation apparent only in cases that recover; even in fatal cases bacteriological investigation after death may reveal that the degree of meningeal suppuration is out of all proportion to the number of cocci present either in films or cultures of the meningeal exudate. There is little doubt that this limited proliferation of the meningococcus is often apparent rather than real, owing to the autolytic tendency of the coccus as well as to the lytic action of the secreted body fluids, both of which tend to liberate its endotoxin. In this relation it is of interest to recall that during the classical researches in course of which he reproduced the essential lesions and symptoms of cerebro-spinal fever in monkeys, and studied the fate of this micro-organism when introduced into the peritoneal cavity of guinea-pigs, or into the spinal canal of monkeys, Flexner observed this same point, and remarked that multiplication on the part of the cocci is not at all essential to the production of the peculiar symptoms and lesions: the meningococcus causing death by a poison liberated from the bacterial bodies.

For the purpose of comparing the pathogenic value of the meningococcus when alive, and when all chance of proliferation is eliminated, a series of experiments has been undertaken, and is still in progress, at the Central Cerebro-spinal Fever Laboratory. In the first place, three specimens of meningococcus were selected of definite pathogenicity to the mouse when introduced alive into the peritoneal cavity of that animal; and the effect on their individual pathogenicity was determined by killing the coccus by ether and then evaporating the warm broth suspension containing it to dryness *in vacuo* at 37° C. A series of falling doses of the suspension of living cocci was injected intraperitoneally into mice, and then duplicates of these doses were etherized, dried *in vacuo*, and next day (or later) redissolved by grinding up in distilled water, and, cultures having been taken to prove that the meningococcus was dead, injected intraperitoneally into mice. Proceeding in this way, it was found that, in the case of two of the meningococci, the coccus was fatal to the mouse in a smaller dose when alive than when killed in the manner described. In the case of the third meningococcus, however—which was a specimen of Type II recently isolated from a rapidly fatal case of cerebro-spinal fever—the coccus was fatal to mice in the same dose when killed, dried, and dissolved in the manner described, as when alive. While it would appear, therefore, that in the case of this particular meningococcus the endotoxin was either exceptionally potent, or more easily extracted than usual, the observation nevertheless furnishes a striking illustration of the great pathogenic importance of the endotoxin of this micro-organism.

It is generally agreed that exotoxin is not formed by the meningococcus in culture. On several occasions virulent specimens of the meningococcus have been cultivated at the Central Laboratory, in flasks of broth enriched by horse serum or by diluted rabbit's blood, and after incubation at 37° C. for a time, varying from a fortnight to a month, a portion of the broth was removed, the cocci contained by

it thrown down by centrifuge, and the clear supernatant fluid injected intraperitoneally into mice. In all cases the mice remained unaffected, so that no evidence has been obtained of the presence of soluble toxin in such cultures.

Up to the present two methods have been employed to obtain a solution of the endotoxin of the meningococcus. The first of these, which is the method favoured by Flexner and Dopfer, makes use of the autolysis of the meningococcus for the purpose of disintegrating the coccus, and setting free its endotoxin. All that is necessary is to make a suspension in saline of a young culture of the meningococcus, then to add some disinfectant such as toluol, and to leave the suspension at 37° C. The cocci undergo autolysis, and a proportion of their endotoxin passes into solution. The second method has been used by Kolle and Wassermann, Kraus, and others. Young cultures of the meningococcus are suspended in distilled water, or in decinormal soda solution, and submitted to agitation for several days in a shaking machine. The suspension is then centrifuged, and the clear supernatant fluid is found to contain endotoxin in solution. It is decanted, phenolated, and kept in the dark in the ice chest.

Neither of these methods would seem to be entirely satisfactory. The autolysate is open to the suspicion that during the process of lysis the toxin may be altered. The "shake extract" is obviously an incomplete procedure. The first step, therefore, in the present investigation was to attempt to find an improved method for the purpose of extracting its endotoxin from the meningococcus.

Besredka's Method of Extracting Endotoxin.

An examination of the literature on the subject of endotoxin soon showed that a method that was likely to be of service was that introduced by M. Besredka, of the Pasteur Institute, in 1905, and used by him and others since with much success for extracting their respective endotoxins from *B. pestis*, *B. dysenteriae*, *E. typhosus*, *B. diphtheriae*, *B. influenzae*, *Micrococcus melitensis*, gonococcus, etc. The method, however, does not appear to have been applied previously to the meningococcus. The procedure of Besredka is as follows:

The growth is removed from numerous cultures of the organism and dried *in vacuo* over sulphuric acid. The dry deposit is then scraped off, reduced to powder in a mortar, and stored in a dry place in the dark. This material Besredka calls "solid endotoxin," and it is found as a rule to be exceedingly toxic to animals. To extract the soluble toxin from it, a weighed amount of the solid endotoxin is mixed with a definite quantity of salt and ground up by hand in an agate mortar most carefully and thoroughly. When the mixture of dried bacteria and salt has been reduced to an impalpable powder, distilled water is added drop by drop, grinding the while, until the proportion of salt present is that of normal saline. The whole process takes about an hour, and at the end the mixture is allowed to stand, and if necessary is centrifuged until all detritus has settled to the bottom. The supernatant fluid, which is slightly opaque, is then removed and its toxicity determined in the usual manner.

In applying this method to the meningococcus a few modifications have been made. In the first place, as the result of comparative trials in which the degree of disintegration of the coccus was followed microscopically, and the toxicity of the extract determined on mice, I have abandoned the salt and use sterile sand instead, the extract being made entirely with distilled water. The procedure is as follows:

A meningococcus is selected of known serological type, and of such pathogenicity that one-tenth part of an eighteen hours' slope culture on tryptic agar when injected intraperitoneally into a mouse produces death within forty-eight hours. Such a culture being available, as many Petri dishes as possible of ordinary tryptic agar are inoculated with it and incubated for eighteen hours at 37° C. It is hardly advisable to work with less than fifty of such plates at a time. To remove the growth, 2 c.cm. of saline is poured on each plate, the growth is then raked off by a bent iron wire, and the suspension poured into a sterile test tube. A film preparation is made from each tube, stained by Gram and examined microscopically in order to exclude possible contaminations. The pure suspensions are mixed and centrifuged at top speed for an hour or more until the bulk of the cocci have been deposited. The top fluid is then thrown away, and the sediment of cocci evacuated into a Petri dish, 5 per cent. of ether added, and the dish placed with the cover off in a desiccator the bottom of which contains sulphuric acid. This desiccator is already connected to a manometer, and also to a powerful vacuum hand pump, designed and made for me some years ago by Mr. Fleuss of the Pulsometer Company. After receiving the dish, the desiccator is exhausted until a minus pressure of about 70 cm. of mercury has been obtained;

the tap is then closed, the desiccator disconnected, and placed in the incubator at 37° C. overnight. Next morning the contents of the Petri dish are seen to be quite dry; the dish is taken out, the deposit scraped off, reduced to powder in a mortar, and examined microscopically. The powder consists entirely of dried bodies of meningococci. It is weighed and stored in a glass-stopped bottle kept in a dry cupboard in the dark.

Before a desiccator is used for this purpose trials must be made to see how much water it will absorb in a night at 37° C. after being exhausted; and care must always be taken to ensure that the suspension of sedimented cocci placed in the Petri dish does not exceed this quantity. The ether is added to prevent the growth of air contaminations, which at first gave much trouble. Once the apparatus is in good working order, the manufacture of dried coccus proceeds without hitch; but microscopical examination both of the suspensions from the plates, and of the dried end-product, must never be omitted. We have found that by this method a hundred ordinary plates of meningococcus yield on an average about 1.8 grams of dried cocci.

Mode of Extracting the Soluble Endotoxin from the Dried Cocci.

A solution of the endotoxin is prepared in the following manner:

0.1 gram of the dried cocci is weighed out and placed with an equal amount of sterilized sand in an agate mortar. The mixture is carefully and thoroughly ground up by hand until the whole has been reduced to an impalpable powder. This generally takes about half an hour. Sterile freshly distilled water is then added drop by drop, and the grinding continued for another half-hour, until 5 c.cm. of distilled water has been added. The mixture is next poured off into a graduated centrifuge tube, and the amount made up to 5 c.cm. if any loss has occurred through evaporation. The tube is stood overnight in the ice chest, and next morning centrifuged at top speed until all detritus has settled to the bottom. The opaque supernatant fluid, which has an appearance somewhat resembling that of concentrated lemonade, is then decanted. This is the standard extract. If it is to be used for rabbits, 0.5 per cent. of phenol may be added, but if for mice intraperitoneally, phenol is better avoided, and a few drops of ether added as a preservative.

When larger amounts are required, successive lots of the dried coccus and sand are ground up and the aqueous extracts mixed.

Toxicity of the Dried Meningococcus and of its Aqueous Extract for Laboratory Animals.

The following are the results in mice and rabbits:

1. *Mice.* It has been found that the dried and powdered meningococcus prepared in the manner described is fatal to mice intraperitoneally in a dose varying from 2 to 10 mg. The results are generally quite regular, provided that the powder is ground sufficiently fine. For purposes of testing samples of serum, chief use has been made of the aqueous extract, the toxicity of which is always determined in duplicate, and the lowest dose at which both mice succumb within forty-eight hours taken as the M.L.D. Mice submitted to the action of the endotoxin of meningococcus become extremely prostrated, and their appearance suggests that the toxin has a direct action on their central nervous system. A proportion of these mice develop diarrhoea. *Post mortem* the right heart is usually dilated, and the spleen is often much enlarged.

2. *Rabbits.* When injected intravenously into rabbits the aqueous extract of the dried coccus seems to act in exactly the same manner as a large dose of the living meningococcus. From some observations carried out in conjunction with Major A. S. G. Bell, it would appear that when a rapidly fatal dose either of the living meningococcus or of the aqueous extract of the dried coccus is administered intravenously to these animals the temperature falls continuously until death, which may be ushered in by convulsions. A similar lowering of temperature was observed by Flexner in guinea-pigs that received a fatal dose of the living coccus intraperitoneally. Rabbits that die from an intravenous injection either of the living coccus or of the aqueous extract of the dried coccus often show *post mortem* petechial haemorrhages. These are especially frequent under the skin, and are thus similar to the subcutaneous haemorrhages seen in some acute cases in man of cerebro-spinal fever.

The aqueous extract of the dried meningococcus contains a considerable proportion of the bacterial protein in solution as well as the toxin. This is evident from the fact, amongst others, that extracts made in the same way from non-virulent meningococci, while containing the coccal endoprotein in solution, show a relatively small amount of endotoxin.

The extract of the dried coccus prepared in the manner described has recently been found to contain a substance lytic for the red blood corpuscles of man and also of the rabbit, mouse, and guinea-pig. From present observations, this substance appears to withstand heating for

half an hour to 60° C., though haemolysis may be delayed by the treatment. The haemolytic substance is present in extracts of the dried bodies of specimens of all four types, and observations are now in progress to determine (1) whether it is the same in all of them, or not; (2) whether it forms, as seems possible, an index to the degree of disintegration of the coccus; and (3) whether the presence of antihæmolyisin in antimeningococcus serum does, or does not, form an index of the presence of anti-endotoxin.

Some further experiments are in progress with a view to determining whether its charge of endotoxin can be increased by passing the meningococcus through a succession of mice. A number of meningococci have been passed through mice without increasing their virulence. In the case of one meningococcus, however—a specimen of Type I from a fulminating case—it was found that, after passage through five mice in succession, the virulence of the living coccus for the mouse had increased tenfold; but, in spite of this increase in virulence for the mouse, no increase could be detected in the amount of endotoxin for that animal contained by the coccus when dried and extracted. This result is of considerable interest because it suggests that, in addition to the charge of endotoxin, another factor may be concerned in the virulence of the meningococcus. The matter is at present being investigated by Dr. C. Shearer, F.R.S.

The antigenic value of the aqueous extract of the dried meningococcus is at present under investigation at the Central Laboratory. From present results it would appear to be serologically specific in much the same manner that the whole coccus is when injected into an animal such as the rabbit.

The Anti-endotoxic Value of Current Examples of Antimeningococcus Serum Supplied for Therapeutic Use.

By extracting their endotoxin in the manner described Besredka and his colleagues have been able to define the anti-endotoxic value of serums prepared against the micro-organisms of bacillary dysentery, plague, and typhoid respectively. It was found that in the case of the particular serums examined by him 1 c.cm. of the antidysentery serum neutralized 2,400 lethal doses of the dysentery endotoxin; 1 c.cm. of the antiplague serum neutralized 200 lethal doses of the plague endotoxin; and 1 to 2 c.cm. of the antityphoid serum neutralized 30 lethal doses of the endotoxin of the typhoid bacillus.

The anti-endotoxic value of antimeningococcus serum has been determined by Dopter and also by Wassermann, Kraus, and their co-workers. Dopter, who used an autolysate for this purpose, considers, as a result of his observations, that 1 c.cm. of antimeningococcus serum suitable for clinical use should neutralize five lethal doses of endotoxin. As a result of the observations of Wassermann and Leuchis, Kraus, and others, who used "shake extracts," it has been laid down that 1 c.cm. of antimeningococcus serum suitable for therapeutic use should neutralize four lethal doses of meningococcus endotoxin. The subdivision of the meningococcus group into a number of serologically distinct types had not been effected at the time when these observations were made.

Now the anti-endotoxic standard laid down for antimeningococcus serum by these observers cannot be regarded as anything but low in comparison with the anti-endotoxic values found by Besredka in case of the three antibacillary serums. Since there is at present no evidence, so far as I am aware, that the endotoxin of the meningococcus is more toxic to the horse than the powerful endotoxins of plague or dysentery, it would seem probable that the relative scarcity of anti-endotoxin in antimeningococcus serum is due to some special difficulty in the case of the meningococcus that has not yet been defined and overcome. For reasons given later the cause is most likely to lie in the form of meningococcus antigen used for preparing the horses. Some preliminary experiments upon this subject will be mentioned.

The method which I have used for testing antimeningococcus serums in respect of their content of anti-endotoxin is as follows:

All the serums are examined in duplicate, and in addition to the specimens of antimeningococcus serum for trial, a control is always carried out with normal horse serum. Two sterile watch-glasses are put out for each serum, and every watch-glass is enclosed in a Petri dish. With a 1 c.cm. pipette, graduated

in tenths, the M.L.D. of endotoxin is measured out into each watch-glass. A measured amount of serum is then added, the covers are replaced, and the Petri dishes placed for thirty minutes in the incubator at 37° C. in order to allow the endotoxin and anti-endotoxin to unite. When taken out of the incubator, many of these serums are seen to have produced an excellent precipitin reaction, which, however, by no means necessarily implies the presence of anti-endotoxin. The contents of the watch-glasses are then injected intraperitoneally each into an individual mouse. The mice are placed in sets of stalls specially designed for the purpose by Major T. G. M. Hine, and are kept under observation for three days.

TABLE I.—*Details of an Experiment in which Five Specimens of Antimeningococcus Serum were Tested against a Minimal Lethal Dose of Endotoxin of Type I and Type II Meningococcus respectively.*

Serum.	Amount.	Type I Endotoxin.	Result.	Type II Endotoxin.	Result.
Normal	0.5	0.2	+	0.2	+
	"	"	+	"	+
A.	0.5	0.2	+	0.2	+
	"	"	+	"	—
B.	0.5	0.2	—	0.2	+
	"	"	—	"	—
C.	0.5	0.2	—	0.2	—
	"	"	—	"	—
D.	0.5	0.2	+	0.2	—
	"	"	+	"	—
E.	0.5	0.2	+	0.2	—
	"	"	+	"	—

+ = Mouse died.

It is clear that in the dose tested (0.5 c.cm.), serum A, in spite of having an excellent amount of precipitin, agglutinin, and, from Captain Tulloch's observations, of opsonin also for the two commonest types of the meningococcus, is deficient in anti-endotoxin to Type I and weak in this antibody to Type II. Serum B, which gave excellent clinical results two years ago, still contains anti-endotoxin to Type I, but is now weak in this antibody to the endotoxin of Type II. Serum C, recently made by pooling the serums of univalent horses, has anti-endotoxin to both these types of the meningococcus. The two remaining serums only neutralize the endotoxin of Type II in the amount tested—namely, 0.5 c.cm.

Now this result cannot be considered satisfactory. The horses providing the serum had received numerous injections of cultures of current meningococci, yet a proportion of these samples of their serum put up for therapeutic use fails to show an appreciable amount of anti-endotoxin for one or other of the two commonest types of the meningococcus in 0.5 c.cm. As the cause almost certainly lies in the kind of antigen used for preparing the horses, a series of observations is now in progress for the purpose of defining the relative value of various preparations of the meningococcus for stimulating the production of anti-endotoxin.

As a preliminary measure the matter is being worked out on rabbits, and if successful, it is hoped, with the co-operation of those who are preparing antimeningococcus serum, to apply the result to horses at present in course of immunization against the meningococcus.

In the first place an investigation was made of the anti-endotoxic value of the serum of a set of rabbits already in course of immunization at the Central Laboratory. Two of these animals had been prepared for over six weeks against first killed, and then living cultures of meningococcus Type I (strain Littledale). Two more had been under similar treatment for the same period against living cultures of meningococcus Type II (strain Harrison). All these rabbits stand intravenously the whole of the growth of an eighteen hours' slope culture of these respective meningococci without more than temporary loss of weight, and without marked symptoms; and their blood contains a good yield of agglutinin for the homologous coccus; yet none of the rabbits contain enough anti-endotoxin in 0.5 c.cm. of their serum to neutralize one lethal dose of endotoxin of the homologous type of meningococcus. Now neither of the meningococci injected into these rabbits is particularly virulent for the mouse—the fatal dose for the mouse intraperitoneally being from one-half to the whole of an eighteen hours' slope culture, and also the dried bodies of the particular meningococci in question have been found to yield but little endotoxin. Some more rabbits, therefore, are at present under immunization with further samples of meningococci of the same two types, but of higher virulence for the mouse, and giving a good yield of endotoxin in aqueous extracts of their

dried bodies. At the same time, further rabbits are being prepared with antolysates of these virulent meningococci, and others with the aqueous extracts of the same cocci after being dried and powdered. The value is also being determined of sensitizing the cocci, or its contents, before injection. By this means it is hoped to define the relative value of each of these preparations respectively of the same meningococcus for exciting the production of anti-endotoxin. It may be of interest to state that one rabbit that had received intravenously a dose of 0.1 c.cm. of the aqueous extract of a virulent example of Type I meningococcus prepared in the standard manner described previously, followed a week later by a dose of 0.2 c.cm., in spite of considerable loss of weight, showed on the sixteenth day after receiving the first dose sufficient anti-endotoxin in 0.5 c.cm. of its serum to neutralize completely a lethal dose of Type I endotoxin for the mouse. Captain Tulloch also found this serum to contain a good yield of opsonin for Type I. Here the matter at present stands.

CONCLUSION.

It would seem, then, that, as regards anti-endotoxin, there is at the present time much room for improvement in, at any rate, a considerable proportion of the samples of antimeningococcus serum supplied for therapeutic use. But it should be stated that several of these serums, though deficient in anti-endotoxin, have been found by Captain Tulloch, who is making a special study of meningococcus opsonins, to contain a good amount of opsonin which in the eyes of Flexner and some other authorities is of almost, if not quite, equal clinical importance. However this may be, few, I think, will deny that it is very desirable that all antimeningococcus serum sent out for therapeutic use as "multivalent" should contain as high a yield as possible not only of opsonins but also of anti-endotoxins capable of neutralizing the toxic principles of the commonest members of the meningococcus group.

The chief obstacle hitherto has been the absence of a trustworthy and simple procedure for determining the amount of anti-endotoxin in antimeningococcus serum. It is hoped that the present method may be found to contribute towards the end in view, because it would seem that some of the best results in the way of lowering the mortality from cerebro-spinal fever during the present outbreak have been obtained by early intrathecal administration of serum that, in addition to a good yield of opsonins, has also been found to contain an appreciable quantity of antibodies capable of neutralizing the endotoxins of each of the two commonest types of the meningococcus.

NOTES ON ASTHMA.

BY

JAMES ADAM, M.D.,

GLASGOW.

SEVENTEEN years ago I put forward the view that asthma is in most cases essentially a toxæmia. More than once in this JOURNAL I have given arguments for this view and have amplified them in my book, and details will not be repeated, but some of the criticisms of that book and much recent writing show that that view is still far from being widely accepted, and yet the proof that asthma is a toxæmia is based not only on the clinical facts but on the best of all evidence—therapeutical success. Of 390 cases about 70 per cent. can fairly be reckoned as cured, or almost so. These cases have come from all parts of this country as well as from some of the colonies, so that "place" has less influence on asthma than was believed.

Among these 390 cases two groups become prominent clinically. One group is that of week-end asthma. The asthmatic attacks in working-class patients tend to appear at the week end, and are clearly associated with the over-feeding and under-exercise of the week end. I have

repeatedly dealt with this point. The only possible explanation of this periodicity is the upset metabolism resulting in a form of toxæmia which induces asthma. This class of case is usually, and for obvious reasons, readily amenable to treatment. This week-end periodicity is not confined to asthma or to man. It is found in some forms of albuminuria, angioneurotic oedema, and epilepsy; also in the "Monday morning disease" of horses (Wood's Hutchinson). The toxæmia in this group is interesting as helping to explain the next group.

The second large group shows a clinical history of bronchitis in children, recurrent year after year, until ultimately what is called spasmodic asthma is diagnosed. The patient may be adolescent or adult before he realizes that he has asthma. In this class eczema is a prominent concomitant. Treatment proves this eczema and this asthma to be due to coddling, to confinement, and to carbohydrate excess, chiefly in the form of milk puddings; for alteration of these conditions means immediate improvement and ultimate cure of the diseases. Here again we have an imperfect metabolism leading to toxæmia, which, in turn, reveals itself in catarrh—of the skin as eczema; of the respiratory tract as various forms of rhinitis, enlarged adenoids, laryngismus stridulosa, bronchitis. This toxæmia acts not only on skin and mucous membrane, but, sooner or later, on the nervous system. And so the catarrhal condition may be accompanied or followed by a spasmodic state, hence—sometimes in combination—urticaria, angioneurotic oedema of the mucous membranes, laryngismus, paroxysmal sneezing, asthma.

Two points are of great importance in this connexion. First, the nose as the respiratory orifice, and the most sensitive area of the whole respiratory tract. If the nose is not right the lower mucous membrane is sooner or later likely to become affected by spasm as well as catarrh; hence, in treatment, attention must be directed to the nose as well as to the toxæmia. Secondly, the widespread connexion of the vagus with the digestive as well as with the respiratory tract has ever to be kept in mind. It is possible the vagus may be directly affected by the toxæmia. All this points to the importance of dietetic treatment, which Hyde Salter so rightly emphasized. Treatment of these two classes of cases is usually soon and absolutely successful; but where the toxæmia has lasted many years, and the mucous membrane has become so altered that *restitutio ad integrum* is not to be expected, the most we can hope for is improvement, though even here the spasmodic attacks may be abolished. I have seen recovery after twenty, thirty, and even forty years of asthma.

Consideration of the circumstances under which asthma arises in domesticated animals goes to support the view that it is a toxæmia. The subject is disappointingly dealt with in British veterinary textbooks, but the account in the American one by Law (1896) is excellent. What he says as to the origin of asthma in dogs and horses exactly bears out what I have written here and elsewhere as to its origin in man. Asthma in dogs "is almost exclusively confined to those kept indoors, over-fed, without exercise, plethoric, and constipated." Everyone is familiar with the wheezy, asthmatic pet pug, but is apt to miss the fact that it frequently belongs to a pampered mistress—fat, wheezy, and asthmatic for a like reason. Law continues: "The disease is one of pet dogs, kept in towns, deprived of exercise, of fresh air, and of the opportunity to relieve the bowels at will; and gorged with highly spiced meats and sweets at least three times a day. Sluggishness and obesity are marked characteristics of the dog when first attacked, though in the advanced stages the violence of the paroxysms and their frequent recurrence may have induced extreme emaciation." And Mr. Dan Hamilton, M.R.C.V.S., informs me that eczema in dogs is caused in precisely the same way. Similarly, Law connects asthma in horses directly with the feeding and want of exercise. Veterinary surgeons have often told me that it is possible to induce asthma in almost any colt by improper feeding. For the following instance I am indebted to Mr. Begg, veterinary surgeon to Lanark County Council. The case is too long to give except in summary; but the details all support the views stated:

A six-year-old van horse, which had cost £46, was seen in January, 1903, on account of asthma, was put in a loose-box, fed on soft oleaginous rations and damped fodder. By the end of March he was reduced to a skeleton—weak, staggering, and

brought almost to his knees by paroxysms of coughing; value £3. He was turned out to grass in April, improved at once, and by July there were no signs of asthma. He was returned to work, but during the following winter, probably owing to the confinement and altered feeding, he developed a less severe attack of asthma. This passed off, and in July he was sold for £40, and was hale and working five years later.

It is likely that many diseases in animals, such as pleurisy and tuberculosis, are lumped together as asthma; but it is trifling with the subject to dismiss asthma in birds as aspergillosis. If the disturbed metabolism arising from over-feeding and under-exercise is the cause of asthma, the bird in which we should most expect it is the canary; and canary breeders are quite familiar with what they rightly call asthma. A bird has naturally a more active respiration and metabolism than man; but a caged canary can get no exercise, and has little to do but feed.

A canary breeder got an asthmatic canary from a neighbour to destroy. It had been fed *ad lib.* on all sorts of seed and other food. He himself had been cured of asthma many years ago, and instead of destroying the bird, thought he would try a plan similar to that I had laid down for him. Instead of filling up its dish with a day's food, he gave it small regular feeds of plain canary seed, and thus cured it. I have had many asthmatic canaries examined by pathologists, who have found tuberculosis in none.

Asthma is probably a disease of civilization. While man had to hunt and kill what he ate, asthma was not likely to arise. An asthmatic visited a Red Indian location in Canada. An old squaw said to him: "You breathe heavy." "Yes; I have asthma." "You English eat too much." "What would you have me do?" She held up two fingers: "Two days no eating." Which was exactly the advice I had given, and which elicited the story. Inquiry among medical friends in various parts of the globe has elicited a number of interesting facts which, however, require sifting, which cannot be detailed here, but of which the following is a summary:

In Central Africa, still uncivilized, there is no overcrowding, the diet is mixed; tuberculosis, asthma, and enlarged tonsils and adenoids are unknown. In China and Manchuria, while the day is largely spent in the open air, overcrowding is common at night; the diet is largely carbohydrate (rice), but no milk is drunk; teeth are often filthy; asthma and enlarged tonsils and adenoids are rare, tuberculosis of glands and lung common. In Siam the life is rather more indoors, the diet more mixed, and milk is drunk and betel chewing common; teeth are filthy; asthma and enlarged tonsils and adenoids not uncommon; tuberculosis greatly increasing. In India conditions vary in different parts and among the different races, but carbohydrate forms a large proportion of the diet, and milk is drunk; tuberculosis is common, asthma also in some parts, but enlarged tonsils and adenoids do not seem to be common.

The inference seems to be that asthma tends to appear in proportion as the life is spent indoors, as there is overcrowding, as carbohydrate forms the staple diet, and as milk is drunk. This about milk is interesting, because my experience proves beyond doubt that asthma cannot be cured when much milk, raw or boiled, is taken. I have cured two cases of hay fever in adolescents who took large quantities of milk by simply cutting it down.

Asthma, then, being in many if not in most cases a toxæmia due to want of adaptation of food, not only to the needs, but to the biochemical peculiarities of the individual, its essential treatment is obvious, simple, but involving much painstaking trouble in every case. I have dealt with this elsewhere at length.

Some think that attention to the nose has been over-emphasized, but, for reasons given above, this is doubtful. After that the main thing is to procure elimination of toxins and prevention of further toxæmia; or, to use Guelpa's phrase, "*Désintoxication et renouvellement des tissus.*" Long before the appearance of Guelpa's book the fact of week-end asthma and the voluntary fasting of the asthmatic during his paroxysm till it ceased had taught me the value of fasting, and it was practised with success. And Hyde Salter sixty years ago rightly took pains with the individual diet. But not enough attention has been paid to cookery. With an unusually irritable *vagus* it is important that the digestive organs be taxed as little as possible.

THE value of the estate of Sir Leander Starr Jameson has been sworn at £45,082 18s. 10d., the net personality being £42,747.

A SURVEY OF 1,064 OPERATIONS FOR THE COMPLETE REMOVAL OF TONSILS AND ADENOIDS,

WITH A CONSIDERATION OF THE POSSIBILITY OF A REDUCTION IN THE NUMBER OF OPERATIONS.

BY

EDWARD D. D. DAVIS, F.R.C.S.ENG.,

ASSISTANT SURGEON, NOSE, THROAT, AND EAR DEPARTMENT,
CHARING CROSS HOSPITAL.

THE consideration of the large number of operations performed for the removal of the faucial tonsils and adenoid growth, or hypertrophied pharyngeal tonsil, makes one pause to wonder whether all these operations are really necessary. It must be remembered that the tonsils, both faucial and pharyngeal, are normal structures present for some definite purpose in every child.

When the tonsils and adenoid growths are septic, diseased, or hypertrophied, so that their presence produces definite and harmful symptoms, every one will agree that they should be efficiently removed, but the predisposing and exciting causes of infection and enlargement of these structures should be reviewed before deciding that operation is necessary. The experience gained by a close study of 1,064 cases, in addition to those seen during seven years in charge of a London County Council school clinic for affections of the nose, throat, and ear, may throw some light on their etiology. The cases have been carefully examined before operation, they have been seen two or three hours after operation, again one week afterwards, and, finally, six months later.

Etiology.

The age at which children require operation varies, but I have not seen one case of congenital enlargement of the tonsils or adenoid tissue, and agree with Lambert Lack¹ in doubting its occurrence. The youngest case was aged 16 months, and there were only five under 2 years. Children operated on under 2 often have recurrence, and the best results are obtained when the operation is performed between the ages of 3 and 6.

The strumous or scrofulous child is a common victim of "tonsils and adenoids" and has a typical appearance with enlargement of the lymphatic glands, phlyctenules of the cornea, excoriation of the nostrils by nasal discharge; such children lack immunity to catarrhal affections and to tuberculosis. This type of child runs in families, several members of the same family are strumous, and there is a family history of tuberculosis, suggesting that the condition is due to a tuberculous predisposition, in addition to bad surroundings in a poor home in a large city. The removal of tonsils and adenoids in such a child, followed by a visit to the seaside with good surroundings and food, leads to a vast improvement in health.

The most marked cases of enlarged tonsils and adenoids amongst children occur in those in whom there is evidence of dirty, badly ventilated, unhealthy homes with their cheaper carbohydrate diet. In these cases parasites, particularly *Pediculus capitis*, are invariably present, and the fact that they cause enlargement of the superficial cervical glands makes one consider what influence pediculi have on the lymphatic tissue of the pharynx. To operate on these children and to send them back to their squalid surroundings is to court failure. The removal of tonsils and adenoids in these cases is almost as illogical as scouring the hair of patients to remove pediculi and immediately allowing them to use the same dirty, infected pillow and clothes. The percentage of well-cared-for children with good surroundings seen in private practice who require operation is much smaller than in the case of poorer children seen at hospital.

Cameron² has shown that excessive carbohydrate diet among the poorer classes, which is the rule owing to its cheapness, produces a catarrhal tendency. Again, there is evidence to indicate that infection—for example, the tubercle bacillus—is conveyed to the tonsils by contaminated water, milk, and food.

The effect of locality is difficult to estimate, and at one time it was found that a large number of the cases came from the low-lying districts of the river banks, and from a valley town where there were watercress beds and a stream running through its centre, but statistics of this

sort tend to be erroneous. In the dry climate of southern Italy adenoid operations are extremely rare.

Scarlet fever, diphtheria, measles, and whooping-cough have been credited with a predisposing influence. Measles certainly has preceded operation in a large number of cases, but since the majority of children have had the various fevers, the estimation of their effect on the lymphoid tissue is difficult. Children with enlarged tonsils and adenoids are much more liable to have acute otitis media as a complication of scarlet fever, measles, and diphtheria.

Some general infections enter the body through the tonsil, and this organ is said to be a portal for infection of the vermiform appendix, for acute rheumatism, tuberculosis of the cervical glands, and, most probably, scarlet fever. Tonsillitis frequently precedes or follows appendicitis, and tonsillitis can be part of a general intestinal infection. Poynton and Paine⁵ record a case of appendicitis following follicular tonsillitis, in which the organisms in the tonsils and appendix were identical; they showed that the appendicitis was a result of a blood infection, and that the cause of appendicitis may be a streptococcal invasion through the blood stream from a follicular tonsillitis. Brian Metcalfe⁴ records two cases of appendicitis immediately following tonsillectomy. Appendicitis associated with tonsillitis is always severe, and requires immediate operation. It is stated that the tonsil is the portal of infection for acute and chronic rheumatism: tonsillitis frequently precedes rheumatism. I have often removed unhealthy tonsils in patients who have had acute rheumatism; also in cases of chorea and chronic rheumatism. In the cases of acute rheumatism and chorea both diseases may recur, and P. R. Cooper⁶ records a case of severe acute rheumatism which followed a few months after tonsillectomy.

In two of my cases, seen three years after enucleation, there had been no return of acute rheumatism, and their general health had been excellent. In one case of erythema nodosum and chronic rheumatism the symptoms had disappeared since enucleation of the tonsils three years before. A similar result was obtained in three cases of chorea.

Mitchell found the bovine tubercle bacillus in the tonsils of fifty-one out of seventy-two cases of children with tuberculous cervical glands and also traced the source of the bacillus to infected milk. Of the tonsils of ninety children with no infection of the cervical glands, 6.5 per cent. gave histological evidence of tubercle bacillus, and 10 per cent. gave a positive result with the guinea-pig. My experience coincides with this result, and in practically all the cases of tuberculosis of the cervical glands (upper deep cervical set) seen the tonsil was unhealthy and required removal. It was a small flat, spongy tonsil, and not a large hypertrophied tonsil.

The most frequent exciting cause of enlarged tonsils and adenoid growth is the common or influenzal cold, measles, or some other specific infection. In a large number of colds there is a mild or even severe tonsillitis—in fact, tonsillitis is frequently called influenza by the patients and their relatives. The doctor is generally asked to see a child during these illnesses, and as the symptoms of a prolonged cold resemble those found when the tonsils and adenoids require removal, an operation is advised; but when the child is seen some time after the cold or acute infection has disappeared there may be no signs of tonsil enlargement or adenoid growth and all the symptoms have disappeared. In cases of this kind it is advisable to wait until the acute infection has subsided before deciding to operate. It occasionally happens when a child is seen during the winter or catarrhal season that the hypertrophy of the tonsils and adenoid growth and the necessity for removal are well marked, but for various reasons operation is delayed until the warmer, drier months of summer, and then the small amount of adenoid growth and the small, normal-looking tonsils removed, make the operator wonder whether he has done an unnecessary operation. This occurrence bears out the fact that the tonsil and adenoid enlargement is often temporary, and that a child should be kept under observation before finally deciding to operate. Removal of tonsils and adenoids before an acute infection has completely subsided, or during the acute stage, leads to increased sepsis, otitis media, suppuration of the cervical glands, and all the septic complications of such an opera-

tion, which, under the best of conditions, is always accompanied by a certain amount of sepsis confined to the wound.

Local sepsis, particularly bad teeth and nasal suppuration, are frequent causes of enlargement and inflammation of the tonsils. It has been my custom for many years to send all tonsil and adenoid cases with bad teeth to the dentist to have the mouth put in thorough order before operation, and no operation is performed until the gums have completely healed. I am in entire agreement with T. B. Layton,⁶ who stated that the number of cases sent for dental care who were found on their return not to require operation was surprising. Even in adults the tonsils will visibly shrink, so to speak, after the removal of oral sepsis. Practically all cases of suppurative tonsillitis or quinsy are accompanied by oral sepsis, and, in a clean mouth, severe follicular tonsillitis will recover without suppuration or abscess. A tonsil and adenoid operation done in the presence of oral sepsis leads to septic complications, particularly otitis media.

Nasal sinus suppuration is rare in children, but the great majority of young adults with nasal suppuration have enlargement of the adenoid tissue of the nasopharynx and tonsils which disappears with the successful treatment of the suppuration. One attack of tonsillitis does not call for removal of the tonsils, but frequent attacks occurring once or twice a year with enlargement of the cervical lymphatic glands (tonsil glands) indicates a thoroughly septic tonsil which requires enucleation.

Causes of Operative Failure.

The first of the common causes of the recurrent operation for removal of tonsils and adenoids is tonsillotomy, or the incomplete removal of the tonsil; the septic stumps are more susceptible to repeated attacks of tonsillitis; I have seen a schoolboy who has had tonsillitis every term after tonsillotomy, and a girl who had nine attacks of tonsillitis in a year following tonsillotomy, and other similar cases.

At a discussion on the relative values of tonsillotomy and tonsillectomy at the International Congress, 1913, the majority present were strongly in favour of tonsillectomy, or complete enucleation of the tonsil. My figures down to 1913 showed that, out of 1,520 cases operated on, 41 had had tonsillotomy performed elsewhere and enucleation of the tonsil stumps had to be done. The examination of another 78 cases of tonsillotomy showed that 39, or 50 per cent., were failures, and in 36 enucleation of the stumps had to be performed. Every surgeon has his own method of enucleation, but the most satisfactory and surest method is that of "dissection" as described by George Waugh.⁷

The second cause of failure or recurrent operation is the performance of the operation by inexperienced and occasional operators. The removal of tonsils and adenoids requires considerable practice.

The third cause of recurrence has to do with the adenoid operation. Children are frequently seen with anterior nasal obstruction, such as a septal spur or marked deformity and deviation of the septum, in which the obstruction is in front of the nasopharynx and produces symptoms and signs of adenoid growth, yet the nasopharynx has been repeatedly scraped for adenoids with no beneficial result. Of fifty-two recurrent operations, ten were due to this cause of nasal obstruction.

Enlargement of the posterior ends of the inferior turbinates has been stated by some to be a cause of recurrent operations, and some operators remove the posterior ends of the turbinates when removing the adenoid growth. I have looked for this condition for many years and have not found permanent enlargement of the posterior ends in children, and I do not consider it necessary to add to the operation by their removal.

There are cases of recurrent adenoid growth, fortunately rare, which, in spite of the fact that the growth has been thoroughly and efficiently removed, require second or third operations, and this suggests that the effect rather than the cause has been removed.

Complications.

The complications of operation are remarkably few, usually remote and due to sepsis. The absence of complications and of any observed disadvantage to the patient

by the loss of the tissues removed will perhaps account for the great popularity of the operation. The immediate complications consist of haemorrhage and shock, both of which are uncommon, more particularly shock. Neither haemorrhage nor shock occurred in any of the 1,064 cases. Most operators see that haemorrhage has ceased, or is insignificant, before the operation is completed. Shock, when it occurs, is the result of insufficient or inefficient anaesthesia.

The remote complications are chiefly the result of sepsis. Acute otitis media occurred in 4 of the 1,064 cases, and one of the four required a simple mastoid operation. The incidence of otitis media can be diminished by careful management before and after operation. It is more common in hospital practice where the patients are treated as out-patients, and is practically absent in private practice where care is taken before and after operation and the patient's surroundings are better. The preparation of the mouth, the avoidance of operation during acute infections, and the rest in bed for three days after operation in a clean home diminishes the incidence of otitis media. In order to avoid operation during an acute infection or in children who are possibly sickening for any infectious fever, such as scarlet fever, measles, etc., the temperature is taken while they are waiting their turn for operation, and if the temperature is above 99° operation is postponed.

Severe scarlet fever and measles are known to follow operation with disastrous results. I have known of two cases in twelve years' experience; such cases do not return to hospital, and are not always observed, but E. W. Goodall and J. D. Rolleston, from a long experience of fever hospital work, both state that they have not seen more than a dozen such cases of scarlet fever or diphtheria following operation in twenty-five and seventeen years' experience respectively. In all cases before operation it is advisable to see that the ear passage is clear and does not contain wax, as a blocked meatus adds to the difficulty of treatment of otitis media. Suppuration of the cervical lymphatic glands is very rare, and I can only remember two or three cases in a period of twelve years; in the series here discussed there were none.

Results.

The results of operations in the carefully selected and well-marked cases are excellent; not only are the symptoms relieved, but there is a great improvement in the general health and comfort, due to the fact that the child sleeps better, its appetite is increased, the hearing improves, the frequent and prolonged colds cease, the flat chest develops, and growth is more rapid. The removal of adenoids in the so-called idiopathic asthma of the nervous, wheezy child has no beneficial effect, and most of these children have no adenoid growth. Idiopathic asthma must not be confused with the intermittent suffocative attacks during sleep, which are due to adenoids, and are cured by the removal of the growth.

A large number of children have attacks of earache and deafness during colds, with retraction of the drums, which frequently suppurate; and if such a case is allowed to continue without operation, the deafness or dullness of hearing becomes permanent, and is beyond cure. The affection of the ears makes operation imperative. In all cases of earache and deafness operated on the ears become normal, except in the older patients, in whom the damage has been done by the long duration of the inflammation. Cases of recent suppuration rapidly heal and the otorrhoea ceases.

The mouth breathing and frequent colds disappear if the patient is made to perform suitable exercises to expand the chest and to promote nasal breathing. No operation is complete unless followed by a course of breathing exercises and the teaching of children to blow their noses efficiently every morning. The parents are told that breathing exercises are as important as the operation, and should be carried out every day for at least six months, commencing a fortnight after operation.

Occasionally a school child will have a temperature, of obscure origin, of 100° with a rise to 102° or more for some weeks following a so-called influenzal cold which on careful inquiry is seen to have been tonsillitis. There is slight tonsillitis with enlargement of the cervical tonsil lymphatic glands. The enucleation of the tonsils cures the fever, and the cervical glands slowly disappear. There are two types of enlargement of the upper deep

cervical set of glands as the result of infection of the tonsils. The first is inflammatory, and accompanies most attacks of acute tonsillitis, and disappears with the tonsillitis. In repeated attacks of tonsillitis the enlargement, which is limited to the tonsil gland of the upper deep cervical group, becomes chronic, but gradually disappears after the removal of the tonsils. The second type of enlargement is tuberculous, is more marked, and there is extension to the other glands of the deep cervical group. If the case is early and the glands are not caseating, removal of the tonsils with suitable antituberculous treatment results in their disappearance, but the majority of hospital cases require removal of the glands in addition to the tonsils.

Nocturnal enuresis has been stated to be due to adenoid growth and its accompanying suffocative attacks during sleep, but in my experience true regular enuresis occurring every night is rarely, if ever, due to adenoids. Very few children with well-marked adenoid growth have this symptom, and I have seen a number of cases of enuresis with absolutely no adenoid growth. Moreover, the removal of the adenoids has not cured the enuresis.

Whatever the function of the tonsil may be its structure and behaviour are similar to that of a lymphatic gland, and it is reasonable to suppose that the remaining lymphatic tissue of the pharyngeal wall, the lingual tonsil, and cervical glands compensate and take on the function of the tonsils and tissue removed, but I have not seen hypertrophy of any of these structures after operation, not even the cervical glands.

I have carefully examined a large number of children six months or more after operation, and have endeavoured to follow up cases, and I have not observed any deleterious effects or disadvantages following removal of tonsils and adenoids. I have not obtained any evidence to indicate that the removal of the tonsils predisposes these children to diphtheria, scarlet fever, or other acute infections, but I have seen several cases of unhealthy spongy tonsils yielding cultures of the Klebs-Loeffler bacillus weeks after the quarantine period had elapsed. E. W. Goodall and J. D. Rolleston both state that in their experience there is no reason to think that children who have had tonsils and adenoids removed are more susceptible to scarlet fever or diphtheria. I have not seen and have no records of tuberculosis of the cervical lymphatic glands appearing after removal of the tonsils.

In conclusion, when a child has a specific set of injurious symptoms which can be definitely attributed to the tonsils and adenoid growth, nothing but benefit results from removal, but there is a need for careful examination and selection of operation cases. An attempt should be made to ascertain and eliminate the cause of the condition under observation before the question of operation is finally settled.

THE TREATMENT OF AMOEBIC DYSENTERY WITH EMETINE AND BISMUTH IODIDE.

BY

A. C. LAMBERT, M.D., C.M. TORONTO,
CAPTAIN R.A.M.C.

DURING the months of July and August, 1917, 40 cases of amoebic dysentery admitted to a military hospital in Mesopotamia were treated with emetine and bismuth iodide, used either alone or in conjunction with emetine hydrochloride.

These cases formed in July 25 per cent. and in August 34 per cent. of all cases admitted in which blood and mucus were present in the stools. They also furnished all the severe cases and the deaths from dysentery during the above period. Four deaths occurred, in two of which hyperpyrexia from the intense heat undoubtedly hastened the end. The remaining two were due to peritonitis following perforation of dysenteric ulcers, and occurred in very debilitated subjects two or three days after admission.

The duration of the disease before admission to this hospital varied from three days to a fortnight, the average being about six days. In many cases a history could be elicited of previous attacks of dysentery in either Mesopotamia or India.

All patients treated were natives of India, and came from widely separated districts of that country. As this was the first opportunity I had of making a trial of emetine and bismuth iodide in a series of cases of amoebic dysentery the diagnosis of which could be confirmed, and the results of treatment checked by microscopical examination of the fresh stools, the following points were considered worthy of investigation:

1. The tendency, or otherwise, of the drug to produce vomiting.

2. Its action, either when given alone, or in conjunction with emetine hydrochloride, in

(a) Acute cases showing active amoeboid forms in the stools;

(b) Less acute cases in which encysting forms are appearing in the stools;

(c) Chronic relapsing cases;

the results in all cases being checked by microscopical examination of the stools.

I. VOMITING.

The action of the drug in producing vomiting had to be taken into consideration, as keratin capsules were not available, and the drug had to be administered in the form of a powder or pill. Happily, it was found that the Indian tolerates the drug very well. The maximum single dose of three grains was never exceeded, and not more than four grains were given during the twenty-four hours. The most suitable dose was found to be two grains, in pill form, given once or twice a day, half an hour after a feed of milk, the pills being freshly made from the powder with a little gum excipient. A few of the cases complained of nausea after taking the drug, and sometimes the patient would vomit an hour or two later, but this was readily checked by the administration half an hour before of 15 drops of tincture of opium; tolerance was established in two or three days, and in no case did it become necessary to discontinue the drug from this cause.

II. CLASSIFICATION OF CASES.

The cases divided themselves pretty definitely into the three classes given above, so that the action of the drug can be considered in its relation to each class.

Acute Cases.

In those cases in which the disease had been present three or four days, and in which several stools containing mainly blood and mucus were passed during the twenty-four hours, microscopical examination showed the presence of numerous amoebae of *histolytica* type. In the treatment of this class the best results were obtained by using 2 grains of emetine and bismuth iodide in pill at night and 1 grain of emetine hydrochloride hypodermically in the morning. A more rapid relief of the acute symptoms was obtained by this method than by the use of either drug alone; in fact, emetine and bismuth iodide, when given alone in acute cases, did not appear to have the same rapid action in relieving pain and tenesmus as emetine, but when used in combination with the latter drug in the above manner it certainly shortened the attack and established a more complete and earlier convalescence. The rapidity with which the stools became faecal and lost their blood and mucus was in some cases remarkable. Furthermore, there did not appear to be the same tendency to constipation, which so frequently follows the use of emetine alone.

The microscopical findings showed a rapid decline in the number of amoeboid forms in the stools after twenty-four hours, and by the end of a week the stools were reduced to one a day, were in appearance normal, and apparently free from amoebae in any form.

Case 1.

Havildar Major, admitted August 5th, 1917, with symptoms of dysentery, had been in hospital a fortnight previously with diarrhoea, which cleared up under salines. No amoebae were found at that time in the stools. On the second admission he was passing five or six stools daily, consisting solely of blood and mucus and containing numerous amoebae of *histolytica* type. Emetine 1 grain hypodermically in the morning and emetine and bismuth iodide 3 grains in pill at night were commenced on August 6th; there was slight nausea, but no

vomiting after taking pill. Tolerance was established after two days. On August 10th the dose of emetine and bismuth iodide was reduced to 2 grains. Blood and mucus were absent from the stool on August 8th, and pain and tenesmus disappeared. Stools one daily, semi-solid, until August 14th, when they became solid and free from amoebae. Returned to duty on August 17th. Total emetine injected, 12 grains; total emetine and bismuth iodide given 28 grains.

Case 2.

Driver, admitted July 23rd, 1917, with severe acute dysentery of four days' duration; passing numerous stools containing much blood and mucus. Active amoeboid forms of *E. histolytica* present. Treatment commenced on July 24th with emetine 1 grain hypodermically in the morning, and emetine and bismuth iodide 3 grains at night. Gripping and tenesmus relieved after twenty-four hours. Blood and mucus in diminishing quantities present in stools up to August 1st. One normal stool passed on August 3rd which was free from blood, mucus, and amoebae. Patient then transferred to another hospital.

Subacute Cases in which Cysts were Present.

In cases which had passed the acute stage when admitted, and whose symptoms consisted of pain and tenderness along the course of the large bowel, more marked over the caecum and lower part of the descending colon and rectum, and the passage daily of two or three semi-solid or liquid faecal stools containing a little mucus and a trace of blood, good results were obtained by giving 2 grains of emetine and bismuth iodide in pill morning and evening, with an occasional dose of $\frac{1}{2}$ oz. of sodium sulphate. Mucus and blood disappeared rapidly under this treatment, the tongue became clean, and the abdominal tenderness diminished, while, so far as could be judged with the laboratory appliances at disposal, cysts ceased to be found after five or six days of treatment. Treatment was continued until a total of 36 to 40 grains of emetine and bismuth iodide had been taken. The diet consisted of milk, sago, and rice pudding, chicken soup, and eggs.

Case 3.

Sepoy, admitted on August 18th, 1917, complaining of diarrhoea, pain, and tenderness along the course of the large bowel and the passing of small quantities of blood and mucus in the stools, of which he had two or three daily. Duration of illness fifteen days. No history of previous attacks. Two and four nuclear cysts found in stools. After a preliminary dose of oil ricini, treatment was commenced on August 19th by giving 2 grains of emetine and bismuth iodide morning and evening. Blood and mucus were absent on August 21st, and the stools were normal and apparently free from cysts on August 23rd.

Case 4.

Driver, admitted on August 16th, 1917, complaining of diarrhoea, with the passage of small amounts of blood and mucus. Two to three stools daily. Illness of about a fortnight's duration. No history of previous attacks. Cysts in stool containing up to four nuclei. Emetine and bismuth iodide in 2 grain doses twice daily commenced on August 18th. Stools normal and free from cysts on August 21st.

Chronic Relapsing Cases.

Under this category are classed cases which had had one or more previous attacks of dysentery from which they had never fully recovered. When admitted to hospital they were very debilitated and anaemic. Usually of the "follower" class, they had continued their duties long after they should have reported sick. The stools passed—often sixteen to twenty in a day—consisted of blood, mucus and sloughs, while not infrequently blood alone was passed, and in considerable quantity. Great tenderness was complained of along the whole course of the large bowel, and there was much gripping and tenesmus. Emaciation was extreme in some cases. These cases furnished all the four deaths occurring during the period under review, and the *post-mortem* examinations showed extensive ulceration and gangrene of the whole of the large bowel from caecum to anus. The stools contained numerous amoebae in all stages of development. Owing to the severity of the symptoms it was necessary to get these patients as quickly as possible under the influence of emetine, in order to destroy the amoeboid forms which were doing such harm to the already damaged coats of the bowel. Emetine hydrochloride, therefore, was given at first in doses of from a half to one grain hypodermically twice daily. Later on, as the symptoms improved, one or two grains of emetine and bismuth iodide were substituted for one of the doses of emetine. Small doses of morphine were used to allay pain and tenesmus, and promote sleep. Stimulants, such as brandy or port wine,

table reading a book, and was increased by eating. It was associated with swelling and redness of the nose, extreme restlessness, and a loss of brain power. I found that this train of symptoms never arose unless the left nostril was seriously blocked.

Some light seems to be thrown on the case by a passage from Purves Stewart's *Diagnosis of Nervous Diseases*, in which he says: "A certain amount of clinical evidence supports the view that there is a special cortical centre associated with the sensations of hunger and thirst. It would appear to be in the temporal lobe at or near the olfactory centre." With regard to the constant "dreamy" feeling complained of by the patient, I found in the same work: "Disease of the tip of the temporal lobe causes a sudden subjective sensation of smell or taste (often associated with a characteristic 'dreamy' mental state)."

I found no evidence of disease of the temporal lobe in my patient. He refused operation for the deflected septum, but I cured him of his attacks of acute blocking by getting him to exercise his alae nasi muscles. A week's exercise in front of the glass gave him well arched nostrils with disappearance of the subjective symptoms, particularly the dreamy mental state.

CHARLES J. HILL AITKEN, M.D.

THE PHENOMENA OF PURULENT BRONCHITIS.

A suspicion arises that many cases which we have hitherto classed as pneumonia of a peribronchial type were really instances of purulent bronchitis. These patients had a very rapid pulse, exceedingly frequent respiration, painful whistling cough, high temperature, headache, profuse expectoration, sometimes purulent, sometimes prune-juice-like. They—or at least the worst of them—had a heavy heliotrope hue of the lips and even of the face. The clinical signs of pulmonary consolidation were indeed sometimes wanting, but the patients were so weak and distressed by movement that one hesitated to harass them by too frequent examinations, and the rapidity of pulse and respiration seemed to justify a diagnosis of pneumonia.

It is suggested that the lesion is really pneumococcal infection supervening on influenza, and that it is infectious. Post-influenzal pneumonia is so convenient and generally accepted a diagnosis that we are tempted to put the label on many doubtful cases, but I submit that the disease is due to a mixed infection—rather an acute pneumococcal septicaemia than a mere pneumonia following influenza. The cases which have been under my care were all of a mixed infection but not necessarily influenza. They were in patients who had had malaria, dysentery, or some form of sepsis. None of the fatal cases were very young. Their lungs were not absolutely free from solid patches, but the parts chiefly affected were the bronchioles, from which grey frothy pus exuded.

The affection is far more fatal than ordinary pneumonia, and the influenzal type is generally contagious, hence the necessity for early diagnosis and isolation treatment. Stimulants freely, with oil of wintergreen externally, and stimulating expectorants combined with nuxvomica and gum resins seem to be useful.

J. C. McWALTER, M.D., F.R.F.P. and S.Glasg.

Dublin.

SYPHILIS INSONTICUM.

As an example how syphilis may be contracted through no fault of the patient, I wish to record the case of two officers who were attended by the same barber in the army somewhere in France. The barber had a sore on his hand which proved to be of syphilitic origin. Both officers developed a rash in due course, and the army doctor diagnosed secondary syphilis, confirmed by a positive Wassermann reaction. One of the officers became a patient of mine, and an independent Wassermann test was positive. I may add that the trouble in my patient's case started on his scalp as a sore.

London, S.W.

N. WALMSLEY.

THE French Government has issued an urgent appeal for the cultivation of the castor oil plant in all suitable localities. It is made not in the interests of pharmacy, but because castor oil is the best lubricant for air engines. The oil was formerly obtained chiefly from South America, but the amount imported is now small. The plant will grow in sheltered situations where it is not exposed to late frosts or rough winds. It is raised from seed, the seedlings being set out about two yards apart.

Reviews.

OBSERVATION AND COMPILATION IN SURGERY.

THE accidents of transport in these days bring together for review two books which present a striking contrast that may perhaps be considered typical of much. The one is a sound piece of clinical observation and deduction, the other a compilation demonstrating once more by its very pretentiousness the German professor's incapacity, when left to his own resources, of throwing any useful light on new problems.

Criticism of the volume on the peritoneum in war surgery,¹ by MM. STASSEN and J. VONCKEN, is disarmed by a foreword of the authors, who wrote in an advanced hospital on the Yser, far from books and without opportunity for laboratory research. But, indeed, the essay calls not for criticism; assuredly not from those who in like circumstances have painfully learnt similar lessons without, maybe, the industry to make a faithful record of their errors and misfortunes, or the candour to describe the tragic steps leading to a settled policy in the face of abdominal wounds. Here we find, well documented by case records, an account of the "false abdomen," the "doubtful case," the extraperitoneal visceral lesion, the parenchymatous-organ solus, the hollow viscus injury, the haematoma, infection. We follow the authors in their recognition of peritonism, simulating true intraperitoneal wound so closely as to be differentiated in the end only by the absence of some one—any one—of all the signs present together in the latter; of genuine wounds devoid of symptoms; of the necessity for sending to the special hospital every wound that might by any chance lead to the abdomen, and especially all those of the upper part of the thighs and the buttocks. We find them at last coming to the decision that in every case the wound should be excised in such a way that the track can be followed right to the peritoneum—and further if need be. To those going fresh to work in a casualty clearing station we commend the study of this book from cover to cover; there is hardly a page which does not disclose an experience or an observation that must be familiar to those who have operated in an advanced abdominal centre, and few, we think, who, even if they do not always agree with the authors, will not admit that these Belgian surgeons have fulfilled their hope and written "*un livre de bonne foy*."

A textbook of war surgery,² a thousand pages long, written by a score or more of the best-known German surgeons, and published after two years of war experience, should prove of great interest, but it does not. Is it that the Censor has cut out all the epoch-making discoveries of Teuton surgeons lest the enemy should profit? or can it be that Teuton surgery has made no extraordinary contributions to the solution of problems common to them and to us? In favour of the former hypothesis there is a notable absence of any reference to a prophylactic for gas gangrene, though there has been some reason, in the greater resistance of the Boche, wounded in like conditions with our own men, to infer or surmise its existence. Be that as it may, the deeper one plunges into this volume the clumsier it appears—clumsy in arrangement, clumsy in attitude of mind, clumsy in treatment. There is little or nothing here to be extracted for the instruction of our M.O.'s in the field or the betterment of their methods. If we turn to any chapter at hazard we find this. The section on the abdomen is from the pen of Schmieden himself, and it is full of good clinical observation, by no means lacking in descriptive power, but it smacks of Halle, not of the front. The real problems of gut injuries through the buttock, the back, the thorax, receive no proportionate share of attention, and the details of technique, from the author of a textbook of operative surgery, are meagre. It is the same with the chest, with the head, with other regions. Fresh from dealing with such work behind the lines one seeks guidance on knotty points, only to be disappointed. Take, again, the question of fractures of the femur; assuredly the British army has nothing to

¹ *Le péritoine en chirurgie de guerre: Etude clinique*. By MM. Stassen et J. Voncken. Paris: Baillière et Fils. 1917. (Roy. 8vo, pp. 160.)

² *Lehrbuch der Kriegs-Chirurgie*. Edited by A. Borchard and V. Schmieden. Leipzig: Johann Ambrosius Barth. 1917. (Roy. 8vo, pp. 988; 5 plates, 429 figures.)

learn if this be German practice. There is nothing really whole-hearted about excision of the wound—nothing to match Sinclair-type methods for securing extension—instead, a final reliance on plaster-of-Paris. No bipp, no flavine, no brilliant green, no chloramine-T, and the Carrel-Dakin method ill understood and discredited. Does one look at the section on the jaws and face, there are at least half a dozen men in the British service who could write a better account of better methods, and expose the whole of their personal results to put the matter to the test. The book is comprehensive, and as a storehouse of the past has a certain value, until a French or British textbook appears. Finally, we cannot but think the illustrations a pain and grief to the soul of Johann Ambrosius Barth—we are sorry, for to him every one is indebted.

BLOOD PRESSURE.

STUDENTS of sphygmomanometry will welcome the appearance of a second edition of Dr. FAUGHT'S *Blood Pressure*.³ It is a comprehensive work; the author has embodied a summary of all the recently published literature dealing with his subject, and has, in addition, given the results of his own research and clinical experience.

The first ten chapters are devoted to physiology. The variations of blood pressure in health, due to such factors as age, posture, exercise, altitude, etc., are fully discussed. In considering posture stress is laid on the fact that pressure is decreased on standing, not raised, as is often stated. The second part of the book deals with abnormal pressures and their significance in conditions ranging from Addison's disease to aviation sickness. Of especial interest are the chapters on hyperpnoea, arterio-sclerosis, and nephritic hypertension. The author insists on the fact, often overlooked, that in certain individuals high tension is a physiological necessity, and is Nature's method of compensation for loss of renal function. Lowering such a pressure will lead to renal insufficiency and must be carefully avoided. It is unfortunate that, in dealing with nephritis, Dr. Faught has treated the various chronic forms of the disease as one group; and his conclusions, drawn from a mixture of cases, are at times decidedly confusing. This disadvantage is, however, compensated by the large amount of valuable information given. Space is devoted to blood pressure in relation to surgery, obstetrics, and anaesthetics. The question of the advisability of operation in patients with high tension is dealt with in a thoroughly sound and practical manner. His final chapters on the use of drugs, and the physical means for controlling blood pressure, will appeal to all who are called upon to treat difficult cases where arterial tension is at fault. Throughout the volume stress is laid on the importance of the regular estimation of blood pressure in nearly all medical and surgical disorders. The advice is good, and should be more generally followed, though we think it is perhaps an excess of zeal which advocates the sphygmomanometer test in the diagnosis of asphyxia neonatorum.

The author's aim, to present in an easily accessible form the pith of medical literature bearing on blood pressure studies, has been achieved with eminent success. Nevertheless, the volume is one to be read with discrimination. As often as not no conclusion is drawn from the mass of evidence produced, and diametrically opposite statements frequently appear on the same page. It is evident that the reader must possess a sound knowledge of physiology and a wide experience of medicine if he would make good use of the mine of information placed at his disposal. The fault, if it be a fault, is one of the subject rather than of the writer, for lack of finality is inevitable in the present state of knowledge. But the immense value of such a survey to anyone about to undertake a study of blood pressure is easily realized, and the book will appeal to all who are interested in this difficult and complicated subject.

THE MENTAL DISORDERS OF WAR.

WHATEVER the effect of the war on the numbers of the insane—and so far there does not seem to be evidence that it has increased the total under care in Great Britain—there is no doubt that it has raised some new

problems, and that some of these have come under the notice of members of the profession who would not in the ordinary way have sought out such cases. We may be grateful, therefore, to Professor JEAN LÉPINE⁴ of Lyons for writing a handbook (in the Collection Horizon) which is intended not to express final opinions but to serve as a guide to medical officers at the front, and especially to those who have had little or no training in psychological medicine. The circumstances of service in the field react on the mind in so many ways and so differently from the influences of peace that new forms of mental disorder may result; but, in addition, they may revive or colour pre-existing disturbances. The repetition of nervous stimuli may lead to a state that may be called psychological anaphylaxis. From analysis of six thousand cases Professor Lépine draws the conclusion that alcoholism was the sole cause in more than a third and played some part in more than half.

Discussion of the numerous acute disorders occupies about half the volume. They are considered in various groups and subdivisions, which are admittedly somewhat artificial. In contrast to the works of German and Russian writers hysterical psychoses receive little attention, at least under that title, and are included under the manifestations of the confusional states. The onset of acute mental confusion is seldom acute, though it may be thought to be so when the prodromal stage has been overlooked. Emotional experiences are the sole or main causes, and thus take the etiological place occupied by toxic or infective agencies in time of peace. A description is given of cases of acute encephalitis of obscure origin with paralysis, which may be extensive, and mental symptoms resembling Korsakoff's polyneuritic psychosis. After reference to the mental sequelae of enteric fever attention is drawn to fits, mania, melancholia, and various tropho-neurotic manifestations after antityphoid inoculation.

The chronic mental disorders being commonly antecedent to the war and less responsive to treatment receive less attention than the acute derangements. Simulation of mental disease is, Professor Lépine says, extremely rare, both because it is difficult and because its success would result in confinement and not in return to a free civilian life. On the other hand, there is considerable risk that the manifestations of mental disease, such as dementia praecox and general paralysis, may be misunderstood and punished by the commanding officers as breaches of discipline. The concluding part of the book is devoted to an explanation of administrative details concerning soldiers with mental disorders.

POPULAR WORKS ON THE PHYSIOLOGY OF NUTRITION.

MEDICAL men are frequently asked by educated patients to suggest the names of books which treat intelligibly of this subject, upon which so much attention is now concentrated. The standard general treatises are not easy reading for the layman. Different aspects of the food problem have been excellently handled by such writers as Professors Hopkins, Wood, Hill, Dr. Spriggs, and Sir William Thompson, but there is still room for two new books addressed to the general public. *An Adequate Diet*,⁵ by Professor PERCY STILES of Harvard, is clearly written, but is perhaps a little too concise, and the author might with advantage have illustrated his arguments more frequently by examples. Professor BAYLISS, in *The Physiology of Food and Economy in Diet*,⁶ has provided a book which can be unreservedly commended. The general physiological principles of dietetics are lucidly explained, the advantages and disadvantages of specific foods are set out, the vexed question of alcohol and its use is handled judiciously, while all the general reader needs to know about vitamins is provided. The food situation changes so rapidly that practical suggestions as to diets necessarily become obsolete soon after they are made, while statistical data of consumption have accumulated during the last few months. Much of the information

⁴ *Troubles mentaux de guerre*. By Jean Lépine, Professeur de Clinique des Maladies Nerveuses et Mentales à l'Université de Lyon. Collection Horizon. Précis de Médecine et de Chirurgie de Guerre. Paris: Masson et Cie. 1917. (Cr. 8vo, pp. 200. Fr. 4.)

⁵ Cambridge: Harvard University Press. 1916. (Fcap. 8vo, pp. 51. 2s. 6d. net.)

⁶ London: Longmans, Green and Co. 1917. (Cr. 8vo, pp. 107. 2s. net.)

³ *Blood Pressure from the Clinical Standpoint*. By Francis Ashley Faught, M.D. Second edition. Philadelphia and London: W. B. Saunders Co. 1916. (Med. 8vo, pp. 478. 15s. net.)

published in our own columns was not available when Professor Bayliss wrote, but none of it invalidates his arguments and much of it strengthens them. There are a few points upon which some difference of opinion is permissible, but none of them are of sufficient importance to need comment, and we believe that the book is one which, if widely circulated, will do great good at the present time.

NOTES ON BOOKS.

THE first set of English translations of the Collection Horizon has been completed by the publication of the translation of the book on *Dysentery, Asiatic Cholera, and Typhus Fever*,⁷ by VINCENT and MURATET. It is edited by Dr. G. C. LOW. Dr. ANDREW BALFOUR, C.M.G., says in a short introduction that, leaving the Western front out of count but taking all the other war areas together, there can be no doubt that dysentery has been the most common of the communicable diseases. At Gallipoli it was extremely prevalent, and accounted for a great deal of the sickness and invaliding which so seriously interfered with military operations. In all the war areas, Dr. Balfour says, the bacillary form has been much more frequent than the amoebic, which accounted for only about 20 per cent. of the whole number of cases. Cholera and typhus have both been kept under control: the native labour corps in Egypt have suffered from typhus fever, but the immunity of the British forces, in spite of the great prevalence of lice, is held to be evidence of the efficiency of the measures taken for disinfection and for "delousing" not only the troops, but the prisoners taken in action. The book is valuable to medical officers, inasmuch as it deals very fully with prevention, diagnosis, and treatment. It is less complete in its handling of pathology and bacteriology.

Lieut.-Colonel W. J. BUCHANAN, I.M.S., C.I.E., has contributed to *Bengal, Past and Present*, an account of his own journeyings through Sikkim and Nepal in the footsteps of Sir J. D. Hooker, as a centenary tribute to that great naturalist, who was born in 1817. J. D. Hooker was the son of Sir W. J. Hooker, Director of Kew Gardens, was educated at the University of Glasgow (M.D. 1839), joined, like Huxley, the Medical Department of the Royal Navy, and went with Ross to the Antarctic when 22 years of age; he returned four years later, and went to India when 30. His first journey among the great mountains was made in 1848, his last and greatest in the following year. Colonel Buchanan, who has himself wandered much in Sikkim, traces Hooker's routes, and provides many notes and explanations. The paper is illustrated by two photographs of the Mt. Everest-Makalu group and of Kinchenjunga, which, even after reproduction and crushing in the post, are very fine. They may make those in populous city pent think that the chance now and again "to breathe the air of Sikkim free" is some compensation for eastern exile. The beauty of the views from Darjeeling is legendary, and Mr. Burlington Smith's diagram of the snow peaks seen from there helps the untravelled imagination to an understanding of what must be the most glorious mountain prospect in the world.

*The New Hazell Annual and Almanack*⁸ for the year 1918, by T. A. INGRAM, M.A., LL.D., is, like preceding issues, intended to provide the information with regard to all the countries of the world, and on topics of the day, which is likely to be looked for in such a work. It contains, for example, lists of members of the Houses of Lords and Commons, of orders of knighthood, and a detailed directory to the Civil Service, lists of societies and institutions, statistics of the British Empire and foreign countries, and a section on agriculture and the world's crops: it contains also a special section on Home Rule for Ireland, and a medical review for 1917, giving a number of abstracts from the medical literature of 1917; these seem to have been judiciously selected, but references are given or omitted in a rather capricious manner. The article on the navy and army is of value, as giving particulars of the various departments of the Admiralty and the War Office; it is illustrated by diagrams of some of the badges of rank in the Royal Navy, the British army, and the United States army. The concluding part of the volume contains a

detailed review of the war, preceded by a summary of events, and followed by an article on the financial aspects of the war, and lists of commissions and committees appointed to consider questions arising out of it. The volume, which is supplied with an excellent index, has been carefully adapted to its purpose.

MEDICINAL AND DIETETIC PREPARATIONS.

Scopolamine Hydrobromide.

IN view of the increasing application of scopolamine-morphine narcosis, Burroughs, Wellcome, and Co. have added to their list two strengths of pure scopolamine hydrobromide in 0.5 c.c.m. sterile solution. The dose of medicament in sterile solution is contained in a hermetically sealed glass phial, which is opened when required for use, and its contents drawn into the syringe. The new strengths are those usually employed, gr. $\frac{1}{32}$, as an initial injection, and gr. $\frac{1}{64}$ for subsequent use. They are issued each in boxes of ten phials.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on Tuesday, January 8th, fifteen cases were considered, and £154 voted to fourteen of the applicants. The following is a summary of some of the cases relieved:

Daughters, aged 76 and 71, of M.D.Lond., F.R.C.S.Eng., who practised at Rochester and died in 1855. Joint income from pensions £90 a year. Present cause of distress due to death of brother who used to help them. They pay 15s. 6d. a week for rent. Owing to high cost of living, unable to manage. Voted £18 in twelve instalments.

Widow, aged 35, of M.R.C.S.Eng. who practised in Liverpool and died in 1914. Left entirely without means, with one daughter, now aged 9, at St. Anne's School, Redhill. Applicant is a chronic invalid, and lives with her mother, who is unable to provide for her. Relieved three times, £35. Voted £12 in twelve instalments.

L.R.C.P. Edin., aged 60, widower, who practised at Old Kirkpatrick. Applicant is suffering from spastic paralysis and is unable to work. His son allows him £50 and he has a pension of £20 a year from another society. Pays £26 10s. for his rooms. Relieved thirteen times, £156. Voted £12 in twelve instalments.

Daughter, aged 51, of M.R.C.S.Eng. who practised in London and died in 1900. Applicant is a confirmed invalid. Only permanent income £5 a year from investments. The Guild allows 3s. 6d. a week. Relieved four times, £58. Voted £18 in twelve instalments.

Daughter, aged 65, of M.R.C.S.Eng. who practised at Watford and died in 1879. Applicant has a pension of £26 from the R.U.K.B.A. Used to earn a little by crochet work, but owing to failing eyesight is unable to continue this. Relieved eleven times, £126. Voted £9 in twelve instalments.

Daughter, aged 63, of M.B.Lond. who practised at Ladbroke Grove and died in 1881. Applicant is practically blind, and receives a pension of £20 from a society for the blind. Has a little help from friends. Relieved five times, £54. Voted £12 in twelve instalments.

Widow, aged 31, of L.R.C.P. Edin. who practised at Leeds and died in 1916. Income just over £100 a year. Has five children, aged 2 to 11 years. Owing to increased cost of food unable to manage. Relieved once, £10. Voted £10 in two instalments.

Widow, aged 47, of M.B.Glasg. who practised at Nottingham and died in 1914. Applicant left with two daughters, now aged 12 and 13, and very limited means. Earns a little by taking in paying guests, but wants help towards the education of the eldest daughter. Voted £10, and referred to the Guild.

Subscriptions may be sent to the Acting Honorary Treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

DR. LEYVA speaks well of the value of injections of sodium persulphate as an adjuvant in the treatment of tetanus by antitetanic serum. He treated three cases in the American Hospital, Paris. The injections appeared to relieve the pain and spasmodic attacks so much that the patients begged for their repetition. The dose is 20 c.c.m. repeated thrice a day of a 5 per cent. solution of the salt in sterilized distilled water. The solution must be freshly prepared and kept cold in a shaded place, as it is easily decomposed.

⁷ *Dysentery, Asiatic Cholera, and Exanthematic Typhus*. By H. Vincent and L. Muratet. With an introduction by Andrew Balfour, C.M.G., M.D., Lieut.-Colonel R.A.M.C. Edited by G. C. Low, M.A., M.D. London: University of London Press. (Cr. 8vo, pp. 227. 6s.)

⁸ London: Henry Frowde, and Hodder and Stoughton. 1918. Thirty-third year of issue. (Crown 8vo, pp. 920 + iii. 5s.)

British Medical Journal.

SATURDAY, JANUARY 26TH, 1918.

THE LAW OF THE HEART.

THE lectureship in physic at St. John's College, Cambridge, founded in 1526 by Thomas Linaere, remained an ordinary college lectureship until 1908, when, after the translation of the then holder, Sir Donald MacAlister, to Glasgow, the college authorities changed the terms of the lectureship and invited distinguished strangers, if this title may be applied to such well-known men as Sir William Osler and Dr. Norman Moore, to give an annual discourse.

Professor Starling's important Linaere Lecture on the Law of the Heart¹ gives an account of his recent researches, and thus differs from the retrospective essays of the two masters of medical history mentioned above. He discusses the mechanism by which the heart muscle adapts itself to the variations in the work imposed upon it by alterations in blood pressure. By means of an ingenious arrangement the isolated "heart-lung preparation" of a dog is provided with an artificial peripheral circulation in which all the mechanical conditions of the heart can be controlled. Two important conclusions are thus at once established: that, provided the inflow of blood remains constant, it is immaterial to the heart what blood pressure within physiological limits (44 to 200 mm. Hg) it has to contend with; and the more the blood pressure rises, the greater the quantity of blood that passes through the coronary arteries; in other words, the more work the heart has to do, the better its blood supply. The heart has a wonderful power of adjusting not only its output of mechanical energy, but also its total chemical changes, to the work occasioned by the mechanical conditions of the circulation. When as the result of exercise the heart receives a larger quantity of blood and has a higher blood pressure opposed to it, temporary dilatation with lengthening of the muscle fibres follows. The change in the muscle fibres brings more active surfaces into play, and this increase in the extent of active surface increases the energy of the heart muscle. At the same time more blood passes into the coronary arteries. The tone of the healthy heart is thus soon restored, and the organ returns to its normal volume, although it is doing more work. In a diseased or fatigued heart, on the other hand, the organ remains dilated during the whole period of increased work, and if the work be prolonged the dilatation may become permanent, and eventually cardiac failure may result.

The important deduction as to the connexion between the length of the muscle fibres and the energy of the heart's contraction justifies the labours of past physiologists on muscle-nerve preparations, the practical application of which was entirely obscure at the time, and in the lecturer's closing words shows that this, like every advance achieved in the quest of pure knowledge, will sooner or later play its part in the service of man.

DISCHARGED DISABLED MEN.

IN France a Government department has been set up to supervise the re-education of men crippled by wounds. It has been placed under the direction of a senator, M. Astier. He takes a wide view of his duties. He recognizes that it is an obligation on the state to re-educate men when crippled in its service, and that the mere grant of a pension, however liberal, cannot suffice to restore them to their place in society. He recognizes also that France, rich as it is, cannot afford to do without the work in industries, agriculture, or commerce, of the thousands of men whose war wounds render them incapable of resuming their former occupations; recent French legislation, while it recognizes the obligation of the state to pension the wounded man and to re-educate him, distinctly places upon him the obligation of submitting to this re-education.

We are very much afraid that things are not going at all well in this respect in our own country. It is the custom to speak evil of the War Office, and it has recently been denounced in the House of Commons as soulless, but in this matter it has shown more sympathy and enterprise than the civilian department which takes over the crippled man when he is discharged from the army. The Military Orthopaedic Department of the army, though it has taken rather a long time to get established on a sufficiently broad basis, and though it is not yet fully equipped, is a very big and well conceived enterprise upon which the country may look with real satisfaction. Sir Alfred Keogh wisely called to his assistance Sir Robert Jones, who has been able to rally round him all that is most progressive in surgical thought in this country. As is clear from the address published in our columns a fortnight ago, Sir Robert Jones is not satisfied; he experiences a divine discontent, but, with the goodwill of the medical chiefs of the War Office and the loyal backing of his consultant colleagues, he has accomplished the greater part of his task, and will win through to complete success. Military orthopaedic centres already in existence cover the whole country fairly well, and in England, Wales, and Scotland there are special hospitals with their workshops and training schools for providing men who have lost limbs with artificial substitutes, and instructing them in their use. We are bound to say that the War Office has been brought to realize its duty towards soldiers crippled in the war. We say nothing of the Navy because the problem has not been so great for it, and, moreover, it has the knack of managing its own affairs. But we are bound to say also that the Ministry of Pensions is not yet doing all that it was hoped it would speedily accomplish for the crippled man discharged from the army. If it be asked why the Army Council allows a soldier to be discharged before he is restored to the best possible condition for earning his own living, the answer is that it is in accordance with the decision of Parliament, which laid it down that when it was established that surgery had done its best for the crippled man, and it was certain he could not be useful again in the army, he was to become the charge of the Ministry of Pensions. The Ministry has made rules and regulations, and it has issued a pamphlet for the use of disabled sailors and soldiers, telling them "how they are being rebuilt at the nation's cost." The motto of this pamphlet is the statement by Mr. Hodge, Minister of Pensions, that "our first principle is restoration," and it tells the men of the advantages of being medically treated and

¹ *The Linaere Lecture on the Law of the Heart.* Given at Cambridge, 1915, by Ernest H. Starling, M.D., D.Sc., F.R.C.P., F.R.S. London: Longmans, Green, and Co. 1918. (Pp. 27; 8 diagrams. 1s. 6d.)

specially trained. It asserts that if a man consents to let the Pensions Ministry try to cure him he will be well looked after. His pension while he is being cured free of cost is put upon the highest scale, and if he lives away from home his wife will get an allowance for herself and the children. It also says that it is most important that a man, after being cured, should be trained for a new job; but, so far as we can ascertain, its arrangements for the continued treatment and training of the men are at present inadequate—that is to say, it has not fully realized the importance of the medical and educational sides of the matter. It is true that a medical department has now been set up of which Sir John Collie has been appointed Director. We wish him success in his new office, but he has a difficult task, and is known to his profession mainly as the author of a book on malingering. The detection of malingering is one of the duties of the Ministry of Pensions, but we should have supposed that the continued treatment and education of crippled men after their discharge from the army was a far more important function, and we are not aware that the new Director of Medical Services for the Ministry of Pensions has hitherto given any special attention to orthopaedics or the re-education of crippled men.

This, however, is not the point of greatest consequence. The important point is that the Ministry of Pensions has not yet got into working order adequate arrangements for helping the men to become useful citizens. There is little evidence that it has any proper organization in contemplation. It has asked the help of the big general hospitals. They will no doubt readily consent to do what they can, but their resources are already very heavily engaged in attending to the needs of the civil population, and there is, we believe, scarcely one which has not set aside a proportion of its beds for wounded soldiers admitted direct from the Expeditionary Forces. We are not always of the opinion of Sterne, that they manage these things better in France, and we know that conditions are different in that country, where every man is by law a soldier and where it has long been recognised that the responsibilities of the individual and the state are reciprocal, but the principles are the same and M. Astier appears to have grasped them. The establishment of a medical department of the Ministry of Pensions is a sign of grace. We hope that early steps will be taken to develop the curative and educational sides of the work and that the Minister will place in a position of responsibility a surgeon with orthopaedic experience, who thoroughly understands the needs of the crippled men discharged from the army and the means by which they may be helped again to the highest possible state of efficiency.

MEDICAL PROBLEMS OF THE AIR SERVICE.

In recent issues we have pointed out the supreme importance of setting up at once a properly organized and independent medical department of the new Air Force; we propose now to deal with particular aspects of the subject which illustrate and enforce our previous contentions.

In the first place, we may advert to the physiological problems of aviation. The response of the organism to massive alterations of barometric pressure has been the object of close study by physiologists ever since the epoch-making researches of Paul Bert, and it is generally known that the work of Haldane and his pupils, Boycott, Douglas, Poulton and others,

together with that of Leonard Hill and his assistants, Macleod, Greenwood, Flack, and others, has provided a mass of information equal in value and superior in extent to that of the German investigators, who still seem popularly to be supposed in this country to have said the last word on all matters physiological. The result is that we possess in England a number of young physiologists who have acquired in the schools of Haldane and Hill a mastery of the special technique evolved by these distinguished investigators. Now the practical problems of high altitude aviation demand for their solution the application of the methods worked out by the physiologists, which cannot be so applied by persons not specially trained. Hence arises the necessity for a special physiological branch—not a mere side show, but an integral part of the service.

Another extremely important branch of physiological inquiry directly relevant to air work is concerned with the study of vision. All physiologists recognize those facts which gave rise to the numerous and conflicting theories of peripheral vision. The researches of Hering, Tschermak, v. Kries, Parinaud, MacDougall, and many others, have given us much information respecting the differing sensitivities to various stimuli of the foveal and extra-foveal retina. The Purkinje phenomenon is a familiar example, as is its development into the complex phases of so-called recurrent vision. The special responsiveness of the extra-foveal retina to stimuli of feeble intensity and its relation to the perception of moving stimuli render the activity of this part of the visual field extraordinarily important for estimating movement and for vision under feeble intensities of light. The rare but well-defined condition of night blindness exhibits the disadvantages of pure foveal vision to an extreme degree. It thus becomes of great practical importance that the vision of the flying man should be investigated by methods which, although precisely defined, are of so technical a character that they are not the possession of the average medical man, and are not even familiar to many whose knowledge of sight testing is above the average. Here again is a branch of pure physiology upon the utilization of which many lives and the fate of momentous military operations may depend. Its right utilization will not be possible without a proper physiological department in the air service. Very similar considerations apply also to the study of the borderland problems which lie between the spheres of the physiologist and the psychologist, but upon these we have not now space to enlarge.

Enough has been said to demonstrate that it is not sufficient to meet the needs indicated with vague phrases about encouraging science. Scientific men must be employed, not only as members of advisory committees—for experience, we regret to say, proves that their advice is frequently ignored—but as executive officers with proper status and powers of action. Finally, we call attention to the necessity of paying heed to another branch of applied science, that of medical statistics. The air service is still young enough to be manageable and old enough to have furnished valuable data, if only those data are intelligently treated. Men of different ages, physique, and avocations, have been recruited, and from their subsequent careers in the service, given an appropriate method of tabulation and analysis, the formulation of sound rules of future selection ought to be possible. It is to be remarked also that the interpretation of experimental results, and the decision whether such results can properly be made a basis for action, always involve some kind of statistical analysis

which can rarely be performed properly save by a statistician familiar both with the subject matter and with analytical methods. At present much useful material may be running to waste, and much useless material may be laboriously collected for want of a scientific man in control of the statistical organization. The notion that a medical statistician is a mere collector of returns and computer of percentages is as prevalent as the idea that a physiologist is a harmless crank devoted to the making of lines upon a smoked drum. Both these beliefs are false and dangerous; especially so in the air service; the method of dealing with the one delusion is equally applicable to the other. It is no longer thought strange that railway managers, coal owners, and multiple shopkeepers should blossom into generals, admirals, and super civil servants. But the conception that a man of science, as such, should be entrusted with executive responsibility is still a suspicious novelty. Thus our contemporary *Aeronautics*, in an otherwise excellent article, meets our plea that a seat on the Air Council ought to be filled by the head of the Air Medical Service, with the remark that it is not likely to find favour, "for several good and obvious reasons which it is unnecessary to enumerate." The "obvious" reason we have just stated; its merit is not obvious.

Of one thing we are sure: if the Air Ministry gives real power to men of science, not the lip service which has so long been their portion, this nation will surely establish a mastery in the air. If science is slighted and despised as heretofore, the new scheme will fail. In the eighteenth century, according to Commander Robinson's history of the fleet, we maintained our predominance by capturing the enemy's better models and then copying them. In these days we cannot hope to live upon the recognition of science by our enemies; we must use our own brains. The air service has an opportunity of beginning well; we hope the occasion will be seized.

DEFECTS IN THE LUNACY LAWS.

IN our correspondence columns this week will be found a letter from the chairman and secretary of a select committee of the Medico-Psychological Association, appointed to resume the consideration of the points in which the existing lunacy laws require amendment. The letter asks medical men to furnish information of their experiences in the defects in the present system of lunacy law and administration, and to suggest legislative alterations they deem advisable. The need for amendment has been accentuated by the many cases of shell shock and other forms of mental derangement in its earlier stages arising out of the war, but reform has long been required in the interests of the civil population. The subject is one to which the British Medical Association has given attention for many years. It has taken an active part in promoting amending bills in the past, and will no doubt continue to show its readiness to work in co-operation with the Medico-Psychological Association. As has very frequently been pointed out in our columns at length, there has been for many years increasing dissatisfaction with the operation of the lunacy laws in England and Wales. Conceptions of mental disease have been changed, and if this country is to keep abreast of the times improvements in the legislation enacted nearly thirty years ago are necessary. The case for reform was very clearly and succinctly stated by Dr. Bedford Pierce in an address on the absence of proper facilities for the treatment of mental disorders in their early stages, delivered before the Yorkshire Branch of the British Medical Association when he was its President in 1915. The address was published

in full in the *BRITISH MEDICAL JOURNAL* of January 8th, 1916, p. 41. Dr. Pierce recognized that the legal profession viewed with grave concern any interference with the liberty of the subject, but pointed out that the problem of the proper treatment of incipient insanity will not be solved until it is clearly recognized that there is no defined line between sanity and insanity. There is a rather vague intermediate zone, and those who enter this region urgently need the best treatment at the earliest possible date; the existence of this intermediate borderland state should, therefore, receive legal recognition. The need for establishing separate clinics in close alliance with the clinics for other departments of medicine is now generally recognized, and as part of them there should be accommodation available for cases that need in-patient treatment. There is no provision for borderland mental cases among the poorer classes, and a move in the right direction would be to permit the admission of voluntary boarders to county and borough asylums, a provision at present confined to licensed houses and hospitals. In Scotland certain cases of temporary or unconfirmed insanity can be dealt with by notification without certification, a procedure which has not yet been adopted in this country.

MARGARINE.

MARGARINE is a generic term for any butter substitute. The original product was made from animal fats, chiefly beef fat, but also mutton fat, lard oil, and horse fat. Nowadays the greater part of the cheaper margarines are made from vegetable oil, chiefly the cheap cocoanut oil expressed from copra, the fleshy portion of the seed of the cocoanut palm. *Arachis* (peanut) oil, is also used, as well as cotton-seed oil; in fact there is hardly an edible animal or vegetable fat procurable in large quantities at a cheap price which has not been used in the manufacture of margarine. The mode of manufacture is in all cases more or less similar. When beef fat is used it is taken fresh and placed in tanks at 80° F., then chilled and cut into small pieces, and raised again to 150° F. The clear oil is drawn off and allowed to set in vats. This is called "oleo-oil," and margarines made from it are sometimes called "oleo-oil margarines." Oleo-oil consists largely of olein. When the margarine is to be prepared, a quantity of skimmed milk is first pasteurized, then cooled, and run into souring tanks, where it is inoculated with lactic acid bacilli and the fermentation allowed to proceed until a degree of acidity is reached which causes rapid precipitation of curd; it is then poured into churns, the oleo-oil or the mixture of oleo-oil and vegetable oils, melted and strained, added, and an emulsion obtained by stirring. This emulsion is drawn off along a slanting board under a spray of ice-cold water, which causes immediate solidification, the mass being broken up into yellow granules. The granular mass, after draining, is matured at a constant temperature while the bacteria introduced by the milk develop; the product is then kneaded into a butter-like mass. To some extent the process of catalytic reduction, or so-called hydrogenation of oils is now carried out commercially; by this method many liquid oils can be rendered solid or semi-solid. These hydrogenated oils do not seem to be much used in this country for making margarine, but are apparently an important constituent of cheap lard substitutes. Early experiments with margarine, made chiefly with the oleo-oil or animal fats, seemed to indicate that a good margarine was of the same relative nutritive value as butter, but there is now reason to conclude that the vegetable margarines may be deficient in the accessory growth substances or vitamins. The presence of growth-promoting accessory substance in association with certain naturally occurring fats was first described by McCollum and Davis, and Osborne and Mendel, and investigation has shown its existence in butter, egg yolk, cod-liver oil, the lower melting point fractions of beef fat and kidney fat. It is

apparently absent from the majority of oils of vegetable origin. The only animal fat as yet found entirely deficient in it is lard. Halliburton and Drummond¹ have recently concluded a very careful research on the nutritive value of margarines and butter substitutes with reference to their content of the fat-soluble accessory growth substance. Confirming and extending previous experiments by McCollum, Hopkins, and others, they found that rats fed upon dietaries in which animal fat margarine was the sole fat and the sole source of the fat-soluble accessory substance, completed their life-circle normally, whereas rats receiving instead vegetable-oil margarines showed a more or less subnormal rate of growth for a short period, and then, sooner or later, the characteristic decline associated with a deficiency of the fat-soluble accessory substance. When the animal margarine was restored to the diet, growth at the normal rate was resumed. The conclusion of Halliburton and Drummond is that the oleo-oil margarines are in this respect nutritively the equivalent of butter, but that coconut oil, cotton-seed oil, arachis (peanut) oil, and hydrogenated vegetable oils contain little or none of the accessory substance, so that margarine prepared with a basis of these fats has not a nutritive value equal to that of butter. Lard substitutes prepared from vegetable oils are equal to lard in their nutritive value, both alike being destitute of the fat soluble accessory substance. The best natural sources of the fat-soluble accessory substances are milk, butter, and eggs, but these have risen in cost, and butter has become very difficult to obtain. There is, therefore, a danger that unless steps are taken to ensure a better milk supply for children they may run some risk of being fed, so far as fat is concerned, entirely upon vegetable-oil margarines, destitute of the growth-promoting accessory substance. The chemical nature of this substance has not been ascertained; it is apparently easily extracted by alcohol, but not invariably by ether. It has been suggested that it is a lipoid and that in plant cells it is held in some form of chemical union, which is broken down during the assimilation of the plant foodstuff by the animal. Some recent attempts to isolate from the small bean, katjang hidjoe (*Phascolus radiatus*), the substance which gives it its power of curing beri-beri and polyneuritis gallinarum, have been reported by Dr. Hulshoff Pol.² They were conducted in Java and at Utrecht. The bean has a great reputation in the treatment of beri-beri and Dr. Pol has used it with success for the cure of that disease. He first made a decoction of the beans and after purifying it administered the fluid to four out of a number of beri-beri patients. These four patients recovered; the others who did not receive the decoction got worse and it became necessary to give them the bean in the ordinary way. The decoction contains an acid principle which yields crystals on evaporation. The chemical constitution of this acid body has not been determined, but there seems little room to doubt its efficacy as a cure for polyneuritis gallinarum.

THE FOOD MINIMUM.

TEN public lectures on some biological problems of to-day are being delivered at University College, London, on successive Monday afternoons. The first, by Professor W. M. Bayliss, F.R.S., on January 21st, dealt in a general way with the food question. He took the daily requirement of a man engaged in moderate muscular work as an amount of food which would yield 3,300 calories; of the sedentary worker 2,500 calories; 1,700 calories was the minimum, and to go below this involved actual loss of body substance. The value of the articles rationed by the Food Controller at present was little more than the bare amount necessary for subsistence, and accordingly, if a person was to do even a moderate amount of work, he must supplement his diet to the extent of some 1,400

calories from unrationed articles. This was a large proportion of the whole, although the unrationed articles included potatoes, fish, and peas and beans. No one would object to living on the smallest practicable diet if necessary, but official statements as to the degree of real shortage were contradictory. If the next three or four months were likely, from the military point of view, to be the most critical in the war, Professor Bayliss suggested that it might be worth while, in order to help every individual to work at maximum pitch, to arrange for a sufficient diet to cover that period, and risk a moderate shortage afterwards. In any case, he agreed with Dr. Leonard Hill that there was a great deal to be said for allowing bread to be completely unrationed and letting other things take care of themselves. From inquiries based on the experience of a number of middle-class families, he had reason to think that the pre-war figure of 4,400 calories given by Hopkins and Wood included an undue proportion of waste in the kitchen, with the consequence that although much smaller quantities of food were now purchased, the people themselves were not sensible of a corresponding shortage in actual consumption owing to greater economy in preparation. It was a part of food economy to keep warm. It had been suggested that in the case of a person who was not obliged to take muscular exercise such exercise should be avoided as it was a waste of energy, and resulted in increased food consumption: but muscular exercise produced heat, and therefore, within limits, it served the purpose of keeping up the body temperature. He had been unable to find any definite evidence for the view that a given weight of protein was more effective for the production of energy than a similar calorie value in fat or carbohydrate. So far as the healthy individual was concerned, protein as a source of energy had no value over any other form of food. Cocoa butter (consisting of the fat removed from the cocoa bean in the preparation of chocolate) might, he thought, be a substitute for dairy butter, at least for cooking; for table use its chocolate taste might be objectionable, but it was an excellent fat.

DISSEMINATED SCLEROSIS.

It is said that after locomotor ataxy disseminated sclerosis is the next commonest nervous disease. Very little is known about its etiology, and it has been looked upon as a primary degeneration. Clinically, however, it presents many signs of a specific infection. The first attack is sometimes a very acute illness, and the recurrences suggest the revival of a latent infection. The anatomical lesions in cases which have run an acute course, consisting of inflammatory and exudative changes in the walls of small blood vessels throughout the central nervous system, are very suggestive of infection. These inflammatory changes are, moreover, present in areas where glia is poorly developed, which is against the idea that a primary degenerative change in the glia is the foundation of the pathological anatomy of the disease. Various workers, including Jürgens, Siemerling and Raecke, and Bullock, have attempted to transmit the disease from man to animals without result. Steiner, just before the outbreak of the war, was able to produce in a rabbit by inoculation of cerebro-spinal fluid from an acute human case, a disease with marked nervous symptoms, which ended fatally about six weeks after inoculation. Since then further experiments have been carried out, the blood and cerebro-spinal fluid from acutely developing human cases being used for inoculation.¹ Guinea-pigs, rabbits, mice, and one monkey have been the subjects of the tests, and the inoculations were made intraperitoneally, intracardially, and intracocularly. The authors describe interesting results in guinea-pigs after intraperitoneal injections of cerebro-spinal fluid, and in rabbits after intraocular inoculations. Control experiments with the blood and cerebro-spinal fluid of patients suffering from other diseases, and of

¹ *Journal of Physiology*, vol. li, p. 235.

² P. Kuhn and G. Steiner, *Med. Klin.*, September 23rd, 1917, p. 1097.

healthy persons, were completely negative. In the guinea-pig the disease may develop and end fatally at periods varying from three days to twelve weeks. The symptoms all point to involvement of the central nervous system. The animal sits humped up, moves about with difficulty, and finally becomes paralysed in the limbs. Death ensues as a rule within about nine hours after the onset of paralysis. In rabbits the symptoms are at first not referable to the nervous system. The animal becomes thin, and its fur dry; later a severe illness sets in suddenly, and ends in paralysis and death. No macroscopic changes have been observed in the experimental animals *post mortem*, and the histological changes have not yet been worked out. Cultures from the blood and from the organs of the animal were one and all sterile. In films of blood both from the guinea-pigs and rabbits, which died with paralytic symptoms, the authors were able to recognize spirochaetes. The methods used were dark-ground illumination, Giemsa's stain, and Loeffler's stain. In only one case were spirochaetes found in the animals by Levaditi's silver method, and then only in the liver. The spirochaetes are described as morphologically very similar to those of spirochaetal jaundice. Under dark-ground illumination they are very actively motile. Further work on the subject is stated to be in progress.

RADIUM IN CANCER.

THE larger number of reports on radium treatment and its results which have been published have been mainly statistical. Dealing with the cases seen during the course of a single year, and with the general methods of radium application, they finish with a short record of the diseases treated and with the results obtained. From the point of view of affording assistance to other workers in the consideration of the actual treatment to be carried out in individual cases, these reports have been, generally speaking, insufficient as accurate guides. In the first report of *Radium Therapy in Cancer*¹ at the Memorial Hospital, New York, by Janeway, Barringer, and Failla, the authors have been at pains to put on record their work in such a manner that it could be used for reference by others, and so that a reader can duplicate the method, or obtain the necessary information to guide him in his own work. The first part deals with the physical considerations relative to the application of radium, and in the course of fifty pages discusses, amongst other things, the various physical and chemical actions, the applicators used, and the value of the radiations from typical applicators. Whilst containing nothing new, it gives in concise and practical form all the information a medical man requires in order that he may approach the actual treatment of cases in a scientific manner. Janeway is responsible for the main portion of the report, which deals with the principles and methods of the application of radium to cancer. It is based on the observation of 424 cases of malignant tumours treated during a period of two years. There are no photographic reproductions of the cases, but a short and concise description is given, together with the exact nature and dates of the radium treatments, and the results, immediate and remote, are described. Similar cases are grouped together, and the observations and results with each group are summarized. The whole constitutes a valuable record of careful and systematic work, and the arrangement is such that the reader is able to obtain information and facts very easily. A short section upon the radium treatment of bladder and prostatic carcinoma by Barringer is based on 25 bladder and 30 prostate cases. A few of these are recorded in the same way as the others, and the opinion is expressed that radium can do as much as surgery for bladder carcinoma without subjecting the patient to the danger and discomfort of a major operation.

¹ *Radium Therapy in Cancer at the Memorial Hospital, New York*. (First Report, 1915-16.) By Henry H. Janeway, M.D., Benjamin S. Barringer, M.D., and G. Failla. New York: Paul B. Hoeber, 1917. (Med. 8vo, pp. 242; 18 figures.)

THE SANATORIUM TREATMENT OF TUBERCULOSIS.

THE city of Birmingham, like other large towns, has to bear a heavy burden of tuberculosis. The measures which the municipality have adopted to deal with it and the progress made during the past year are set forth in a long report by the tuberculosis officer, Dr. G. B. Dixon, with supplementary reports from the superintendents of the hospitals and sanatoriums included in the scheme. It is satisfactory to note that an attempt has been made to separate the advanced from the more curable cases, but complete success has not yet been attained in this respect. In Birmingham, as elsewhere, the demand for sanatorium treatment considerably exceeds the supply of accommodation, and many beds, primarily intended for first-stage cases, have to be given up to patients for whom there is no real hope of recovery, many of them being Poor Law cases. Dr. Dixon points out very clearly the difficulty which attends the classification of early cases, some of which, without any marked physical signs of disease, may go rapidly downhill, while others with well-established evidence of destruction of lung may make a good recovery. Doubtless this is true of a small proportion of cases, but in the vast majority of instances the cases which can be restored to permanent working capacity are those in which the actual pulmonary lesion is still only slight. Restoration to working capacity for a few months or years is of little value to the community, and experience proves that it can be attained in the chest hospitals as well as in the sanatoriums. Hence it would be more gratifying if the Birmingham method could be carried out in its entirety and the sanatoriums strictly reserved for the treatment of cases which exhibit substantial evidence of curability. Almost every aspect of the subject is dealt with in the report, except the durability of working capacity; it is only compared as before and after treatment. The dangers of family infection are shown diagrammatically, which serves to confirm the fact observed in other large centres that the presence of near relatives affected with tuberculosis is the main danger; the figures point unmistakably to the overcrowded bedroom as the probable scene of infection. A very large number of tuberculous children have to be dealt with in the Birmingham area, and the arrangements made for combining treatment with preliminary education are excellent. Working from an antituberculosis centre in the town, the investigation of notified cases and contacts is carried on very thoroughly and there are five institutions set apart for the reception of selected cases. Every effort is made to re-examine cases after a period of treatment in these hospitals and sanatoriums and to keep in touch with them later on, but the inevitable shortage of skilled observers greatly hampers this part of the work. The high percentage of disappearances of bacilli, even in third-stage cases, is remarkable and contrasts strongly with observations made upon this point in some other sanatoriums, especially in face of the fact that many examinations of sputum were made several months after the patients had returned to their normal round of life. Very close supervision is maintained over the milk supply, and all cows reacting to tests are eliminated, although apparently in perfect health. The high case-incidence among children would seem to show that in spite of all these precautions the insidious encroachments of the bacillus have not been checked. The ever-present danger to young children is emphasized also in a report from Belfast to which we lately referred.¹ In that city there has been a remarkable tendency to glandular tubercle, and the same thing has been noted in other large towns as occurring during 1916. Examination of contacts proved the presence of a great deal of latent disease for which no medical aid was sought, and indicated very clearly the need for more complete domiciliary investigation and treatment. Too often, for lack of early recognition, the disease gets the upper hand and advances to the incurable stage before the need for medical help is thought of.

¹ BRITISH MEDICAL JOURNAL, November 10th, 1917.

THE WISE USE OF MEDICAL MAN POWER.

IN an article upon this subject last week we stated that it was hoped that it might prove possible to avoid further calls upon the civil profession to supply more medical officers for the army, but that the calls from the Royal Navy might become more insistent. It appears that this statement without qualifications has been misunderstood. Its truth was contingent upon the army obtaining all the newly qualified medical men on a principle of equitable adjustment with the Royal Navy. This, it was thought, would be understood, because the claim of the medical services of the armed forces on newly qualified men is so generally recognized that it did not seem necessary to reiterate this point. It seemed probable that from this source the actual wastage of the medical services by invaliding, owing to wounds or sickness, would be met. But the statement was made subject to another contingency which ought to have been specified—namely, that the number of temporary officers R.A.M.C. relinquishing their commissions at the end of the period for which their contracts run and the number of demobilizations did not increase. Should any such increase occur on a large scale the balance will of course be disturbed, and what steps should be taken in that event will become a serious matter for consideration between the professional committees, the Ministry of National Service, and the medical services of the Royal Navy and of the army. The question of medical man power was mentioned during the discussion of the quarterly report of the Central Medical War Committee at the meeting of the Council of the British Medical Association on January 23rd. It was decided that a communication should be sent to the Minister of National Service urging the need for publication of the findings of the Committee of Inquiry which visited France last September to inquire into various matters connected with the personnel and administration of the Army Medical Service in that country, and the importance also of ensuring that any recommendations made by that Committee with a view to economy of medical man power shall be carried into effect.

Medical Notes in Parliament.

Abolition of Boards of Guardians Recommended.

(From Our Parliamentary Correspondent.)

MUCH interest attaches to a report which has just been presented to Dr. Addison, as Minister of Reconstruction, by a committee that has been considering questions of Poor Law reform. Far-reaching changes, involving the abolition of boards of guardians and the transfer of their functions to county and borough councils, are recommended. The Committee was appointed by the President of the Local Government Board, and not by the Reconstruction Minister as might be inferred from what has been said in the lay press. It is only because Dr. Addison gathers up from all the departments matters which concern reorganization after the war that he has the report under review. Sir Donald Maclean was made chairman of the Committee, whose membership included Lord George Hamilton and Mrs. Sidney Webb, the authors respectively of the majority and the minority reports of the Poor Law Commission appointed by the late Lord Salisbury when he was Prime Minister.

The Committee recommends the abolition of boards of guardians and the merging of all the functions of the Poor Law authorities in those of the county council and the county borough council, subject to certain modifications set out in schemes for London and the other administrative counties. After enumerating the many public authorities dispensing assistance out of the rates and taxes, the Committee states that its recommendations have been made for the further unification of services. The Committee has adopted for its guidance the principle of concentrating as far as possible on one local authority in each area the administration of all expenditure from public funds.

As regards matters more directly referred to it—by the

Local Government Board—the Committee recommends that the care of the sick and infirm, including maternity and infancy, and the aged (who need institutional care) should pass to the county or borough councils according to area; and that the provision for children able to attend school and for mentally deficient persons should similarly pass. In other words, it proposes *inter alia* that workhouses, Poor Law homes for children, and the care of mentally defectives should be transferred to the councils. The recommendation is to the effect that the workhouses, under another name, with the care of the mother and the young child, the sick and the old, should be put under the administration of the existing public health committees of the councils, which should be called Health Committees. It is recommended that the children of an age to attend school should come under the charge of the existing education committees of the councils; and that mentally defective persons and those of unsound mind uncertified should come under the charge of existing committees of the councils formed under certain Acts of Parliament.

For two other classes at present dealt with by boards of guardians it is proposed that two new committees should be set up by the councils. The first of these classes consists of the unemployed able-bodied, and it is recommended that the county or borough council should set up an unemployment and training committee, on the lines of the education committees, on which employers and trade unions should be represented. For dealing with the other class, including those who receive Poor Law out-relief, it is recommended that each of the councils should set up a home assistance committee. This committee would, besides taking up the administration of "outdoor" relief, as it is termed, deal with old age pensions, and it might possibly take up the provision of meals for school children, now made under an education Act; it might also deal with cases of discharged soldiers and their dependants requiring attention.

It is recommended that compensation should be given to officers (including medical officers and nurses) displaced or injuriously affected by the absorption of staffs. The proposal is that option as to transfer should be given both to the councils and to officers concerned, and that tenure of office and all rights of superannuation should be fully taken into the reckoning.

As regards the County of London, it is proposed that the functions of the boards of guardians, the Metropolitan Asylums Board, the managers of any sick asylum districts, and Poor Law school districts, should be divided between the county council and the borough councils, according to a scheme to be framed by the county council after consultation with the borough councils. The City of London is to be reckoned for this purpose as if it were a borough. The work of the assessment committees throughout the country would be taken over by the councils. The report is signed by all the members of the Committee subject to qualifying memoranda by certain individual members.

The fact that the report is being considered by Dr. Addison has led to the inference that it is intended (if it should be adopted by the Government) for application after the war. The Committee, however, does not, it is understood, make any recommendations as to when its proposals should be taken up. Some of its members are said to favour the view that it would be better to proceed promptly, in order that our system might have been reorganized when demobilization takes place, bringing, perhaps, greater calls for what is at present Poor Law relief. Other members of the Committee very possibly regard this as one of the questions that can hardly be settled in the midst of the war.

The report has already come under the attention of the Association of Poor Law Unions of England and Wales, of which Mr. John Spear, M.P., is president. It should be said that this body has been watching the matter for months past. When the Local Government Committee was first appointed the association sought to have representatives placed upon it, but were informed that the Committee was not set up on a basis of representation of public and other bodies, and therefore the request could not be granted. Questions have been addressed to ministers in the House of Commons from time to time, with the object of getting the decision reconsidered, but they were met with a negative.

A copy of the report was, however, through some medium made available for consideration by the association

at its meeting in London last week, and was discussed at length. The Association has for some time been preparing a scheme for the reorganization of boards of guardians. Amongst other proposals which it contains in draft is one for the abolition of the term "workhouse" and of other words which jar on present day feeling. It is thought that the phrase public assistance, or some such words, should be substituted for "Poor Law relief," and that thus the stigma of pauperism could be removed from the help given to those who are broken by misfortune. This scheme will shortly be ready for submission to Dr. Addison, and it is understood that he is prepared to weigh it carefully. Some such assurance is understood to have been received.

The Poor-Law Association holds very distinctly that there are strong arguments against boards of guardians being "scrapped," to use the expression of one of its members. It is urged that the committees existing and to be appointed by the councils would not have the same direct responsibility to the people because the election of councillors is on so many issues, and also because of the nomination of non-elected members. It is submitted that the election of boards of guardians by the people affords the best security for administration in the interests of the poor with due regard to those of the ratepayers. Persons who have not the time (and in some instances the means) to enable them to become county councillors serve in their own localities as guardians, and they are in close touch with the people. The view is also taken that the transfer of the work of the assessment committees to county councils, which is consequently recommended to effect complete transfer, is undesirable, this important work being in experienced hands, and generally reckoned to be well performed.

The Man Power Debate.

In the course of the debate on the Man Power Bill last week Sir Donald Maclean (Chairman of the London Appeal Tribunal), warned the Government against expectation of getting more than a few men through the tribunals. He said that in two years the London Appeal Tribunal had given 50,000 decisions in respect of 40,000 cases, and out of these 40,000 only 3,000, including the conscientious objectors and men with special certificates, were running under exemption. In London they had got down almost to the bone. He asked that some general instruction should be given to the tribunals as to Grade 3 men (Army Auxiliaries), otherwise they would, though mainly unfit, be sent into the army. There were many cases in which a man was, *prima facie*, fit for the army, and yet if he were sent his death warrant was signed. Referring especially to cases of men over 35 years of age, he mentioned that the sickness casualties of men between 35 and 40 years of age were 250 per cent. more than those of men between 28 and 35 years of age. Sixteen per cent. of the pensions given were for sickness and disease. He complained of the system under which men were dealt with when they got into the army, and said that "colossal stupidity" was revealed.

Mr. E. Smallwood, the new member for East Islington, in a maiden speech in the same debate, urged that the War Office needed combing out. He spoke with some feeling, as he had lost both his sons in the war. He alleged as regards the younger son that there was discourtesy when he tendered a certificate signed by Sir Thomas Barlow for extended leave. As regards the other son, Mr. Smallwood told a painful story. It appeared that this young officer was in a military hospital in France, and Mr. Smallwood was not permitted to stay at his bedside the night he died, but had under regulations to leave the hospital. He was told by the matron that the rule must be kept. Mr. Smallwood quoted these experiences to insist that the War Office was soulless, and that changes were needed.

Orthopaedic Treatment of Discharged Soldiers.—Major David Davies asked the Pensions Minister whether he was aware that, with the exception of the Wrexham garden village training centre, there was at present no technical training centre or orthopaedic institution for special treatment available in North Wales, and whether he would consider the advisability of amalgamating the two Joint Statutory Committees of North and South Wales, so that the requirements of discharged soldiers in Wales might be dealt with by one committee, which would have regard to the provision of training and treatment for the whole of Wales. Mr. Hodge, in reply, said that he had no power to amalgamate the two Joint Committees, which were voluntary associations of local committees, and he doubted whether such amalgamation would be desired by either body. Their separate existence, however, was not a bar to the common use of institutions and training centres in Wales. The hospital at Llandrindod Spa, which he was arranging, would take 150 cases, and would be available to the whole country, as was Wrexham already, for orthopaedic treatment. The general arrangements for training included the transfer of a man from one area to another when necessary.

Hospital Treatment of Discharged Disabled Men.—In reply to Sir Henry Harris, who asked the Pensions Minister whether he had come to any agreement with the London civilian hospitals as to the terms and conditions on which discharged disabled men would be treated, Mr. Hodge said that arrangements had been made with both London and provincial hospitals, and the terms would be communicated to all Local War Pensions Committees forthwith. In reply to another question by Sir Henry Harris, Mr. Hodge said he was fully aware of the difficulty experienced in London in obtaining in-patient treatment for discharged disabled men. It had been arranged that the War Office, recognizing the prior claim of the Pensions Ministry to the accommodation in civil hospitals, would refrain from requisitioning further beds in these hospitals, and would release the accommodation now occupied by it as rapidly as possible. Sir Henry Harris further asked whether Mr. Hodge would take steps to supplement the inadequate accommodation, having regard to the claims of ordinary civilians, and quite apart from military needs. Mr. Hodge said that a Medical Department had just been instituted at the Pensions Office, and was presided over by a very eminent surgeon. This department had the matter of hospital accommodation in hand. He was hopeful that under expert advice the difficulties referred to would be rapidly swept away. Sir William Collins asked if Mr. Hodge was aware that more than 1,600 beds had, since the beginning of the war, been added to the accommodation of the voluntary hospitals in London in order to meet the case of the admission of military patients.

National Service Medical Boards.—In reply to Mr. Snowden, Mr. Beck said that all members of the National Service Medical Boards were civilian medical practitioners. Certain of the presidents of the recruiting medical boards continued to act as chairmen of the National Service Medical Boards during the period of transference from the control of the Army Council to that of the Ministry of National Service, but these had now been relieved with the exception of two, who would be relieved within a few days. The President of the Recruiting Medical Board at Derby relinquished his position on December 1st, 1917, and had been succeeded by a well known highly qualified civilian medical practitioner. Inquiries were being made regarding the alleged conduct of the late President of this Board.

Discharged Soldiers and National Work.—Replying to Mr. Hogge, Mr. Beck stated on January 21st that it was proposed that men at present in civil life who had served in the forces and been discharged on account of disablement or ill health, and who were liable to re-examination and recall for service, should have an opportunity of engaging in work of national importance instead of re-entering the army. The work of national importance would be in an industry contained in a list to be settled. Each man must take steps to apply for employment, but every facility would be given him. Hitherto the concession had applied only to men who had served overseas, but in future it would apply to all who have served and been discharged or disabled. It would not apply to men who, without having served in the forces, have been exempted by the tribunals.

The Army Council and the Army Medical Service.—Major David Davies asked Mr. Macpherson whether, in view of the resignation of Sir Alfred Keogh and the appointment of his successor, the War Secretary was willing to consider the question of direct representation on the Army Council of the Royal Army Medical Corps, thus raising the status of the Army Medical Service. Mr. Macpherson replied that it was not intended to place the Director-General of Army Medical Services on the Army Council, but whenever matters affecting medical organization or administration were before the Council, the Director-General would be called in to give the Council the benefit of his advice. Major Davies asked whether it was true that Sir Alfred Keogh was offered a seat on the Army Council. Mr. Macpherson said he was not aware whether this was so.

UNDER the heading "Be careful with lithotripsy in the wounded," *Prætorius (Muench. med. Woch., August 14th, 1917)* records the case of a soldier wounded in the back by a mine explosion. Several projectiles were removed from his back and the wounds healed quickly, but cystitis, which developed soon after he was wounded, became steadily worse in spite of irrigations and drugs given by the month. About six months after he was wounded the urine was alkaline and contained a considerable amount of pus. The cystoscope showed diffuse chronic cystitis, but no scar or ulcer of the bladder. A somewhat elongated white stone, a little larger than a pigeon's egg, was seen, and a lithotrite was accordingly inserted. The crushing of the stone required only a few minutes, but as the last fragments were being demolished the lithotrite jammed, its blades remaining 2 to 3 mm. apart. Attempts to withdraw the lithotrite were so painful that a general anaesthetic had to be given, and even then the end of the lithotrite could not be pulled back further than to the middle of the anterior urethra. The urethra was incised at this point, and with the greatest difficulty a jagged piece of sheet iron was removed; the lithotrite was then easily withdrawn.

THE WAR.

THE WESTERN FRONT.

APRIL-NOVEMBER, 1917.

THE report of Field Marshal Sir Douglas Haig, describing the operations from the opening of the British offensive on the Western Front in April to the conclusion of the Flanders offensive in November, begins by describing the general allied plan as originally formed in November, 1916, and the modifications subsequently introduced. He describes the battle of Arras which opened on April 9th and was the main feature of the spring campaign, the battle of Messines which opened on June 7th, the third battle of Ypres which began on July 31st, the numerous counter attacks which followed each of these actions, and the various subsidiary operations. The Arras operations yielded 19,500 prisoners, among whom were over 400 officers, and 257 guns, including 98 heavy guns. The captures in Flanders amounted to 24,065 prisoners and 74 guns, besides machine guns and trench mortars. The total number of prisoners taken in the period under review was 57,696 including 1,290 officers. The dispatch concludes with a number of paragraphs dealing with the various branches among which is the following referring to the work of the medical services:

Medical Services.

The work of the Medical Service in all its branches has continued to afford me most valuable assistance. The high standard of efficiency displayed by all ranks of the medical service has resulted in an almost entire freedom from epidemic disease, and has been the cause of much saving of life and limb amongst the wounded.

The devotion and gallantry of the Royal Army Medical Corps and of the Medical Corps of the Overseas Dominions during the recent operations have earned universal admiration and praise. Their work of collecting the wounded from the front has been of an exceptionally arduous nature, owing to the condition of the ground and weather. I regret that so many gallant officers and men have lost their lives in carrying out their duties.

The Medical Service of the United States of America has shared in the work of the British Medical Service, and has given very valuable help.

I am much indebted to the devotion and work of the consulting surgeons and physicians and to the Auxiliary Services of the British Red Cross Society and Order of St. John of Jerusalem.

The Nursing Services, several of whose members have unfortunately lost their lives from hostile air raids, have, as always, devoted themselves with untiring care and zeal to their work of mercy.

The excellent organization and administrative work of the Medical Services as a whole have given me entire satisfaction.

CASUALTIES IN THE MEDICAL SERVICES.

Drowned.

SURGEON PROBATIONER L. P. ST. J. STORY, R.N.V.R.

Surgeon Probationer L. P. St. J. Story, R.N.V.R., was reported as drowned, in the casualty list published on January 21st.

ARMY.

Killed in Action.

CAPTAIN A. K. SINHA, I.M.S.

Captain Atul Krishna Sinha, I.M.S., was reported as killed in action in the casualty list published on January 18th. He had been previously reported as missing so long ago as August 23rd last, shortly before which date his death must have taken place. He was born on August 4th, 1888, and educated at the Calcutta Medical College, graduating M.B. Calcutta in 1912, and at University College Hospital, taking the diplomas of M.R.C.S. and L.R.C.P. Lond., and also the Cambridge diploma in tropical medicine and hygiene in 1913, and the M.R.C.P. Lond. in 1914. He entered the I.M.S. as lieutenant on July 26th, 1913, and was promoted to captain on July 26th, 1916.

Died on Service.

BRIGADIER GENERAL A. A. HOWELL, C.M.G.

Brigadier General Arthur Anthony Howell, C.M.G., died suddenly at Blackdown Camp on January 15th, aged 56.

He was born in 1862, the third son of the late Very Reverend David Howell, Dean of St. David's, and was educated at Shrewsbury School and at the London Hospital, taking the diplomas of M.R.C.S. in 1886, and the L.R.C.P. Edin. in 1891. He was in partnership practice at Worplesdon Hill, Brookwood, Surrey, where he was medical officer to the post office. He had held a commission in the auxiliary forces for many years, and attained the rank of lieutenant-colonel commanding the 3rd Territorial (City of London) battalion of the London Regiment, the Royal Fusiliers, on March 8th, 1910. He was given a brigade in 1916. He was also a member of the City of London Territorial Force Association, and held the Territorial Decoration. He served in the South African War in the City of London Imperial Volunteers, and gained the Queen's medal with four clasps, also being granted the honorary rank of captain in the army from December 1st, 1900. In the present war he was twice mentioned in dispatches, and had received the C.M.G. and the Russian Order of St. Anne.

Lieut.-Colonel R. R. SLEMAN, R.A.M.C.(T.F.), writes: It was a shock to many to hear of the death of Anthony Howell. He had as recently as January 10th attended a meeting of the City of London Territorial Association at the Mansion House and made an excellent speech. On January 15th he died suddenly at Aldershot. Howell commenced his military career as a volunteer medical officer, but soon took up a combatant commission, and at a time when the Territorial Force was not fashionable he raised a battalion of the London Regiment up to full strength; the men were of exceptionally good physique. Soon after the mobilization of the Territorial Force in 1914 Howell took his battalion East, and eventually it went to France and did splendidly, made its famous charge at Loos, and was commended in Lord French's dispatches. Howell was made a C.M.G., and later a substantive Colonel in the Territorial Force and a temporary Brigadier General. It is believed that this is a unique position for a medical man to hold. He was successful as a medical man in practice, and as a soldier he was a good disciplinarian, and always had the courage of his opinions. In South Africa he accompanied the march of the C.I.V. of a thousand miles, and did most of the journey on foot.

COLONEL J. B. MANN, R.A.M.C.

Colonel John Bently Mann, R.A.M.C.(T.F.), died at Manchester on January 15th, aged 56. He was the youngest son of the late Mr. Robert Manners Mann, surgeon, of Manchester, and was educated at Owens College, taking the diplomas of L.R.C.P.I. in 1884 and the M.R.C.S. in 1885. He was surgeon to the Manchester and Salford Lock Hospital, medical officer of No. 1 District and public vaccinator of No. 3 District of Manchester Union, and medical officer to the post office and telegraph department in Manchester. He joined the Manchester Volunteers as medical officer in 1886, and rose to be A.D.M.S. of the East Lancashire Division (T.F.). He went with the 42nd Division to Egypt in 1914 and served with them in Gallipoli, whence he was invalided with dysentery, which finally caused his retirement from the service. He was also a member of the Lancashire Territorial Force Association, and held the Territorial Decoration.

Prisoner of War.

Captain F. M. Walker, M.C., R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Forman, Ian Charles, Captain Canadian Light Infantry, eldest son of Dr. C. W. Forman, of the American Presbyterian Mission, Umballa, Punjab, killed in November. He had been at the front for over two years.

Greany, John Wingate, D.S.O., Captain Duke of Edinburgh's Wiltshire Regiment, eldest son of Surgeon-General John Philip Greany, I.M.S.(ret.), of Ealing, was reported wounded and missing on April 9th, 1916, and is now presumed killed from that date. He was at Oxford when the war began, and at once joined the Wiltshire Regiment, attaining the rank of captain on March 5th, 1915. He had served with his battalion in Gallipoli, where he gained the D.S.O., and went with it to Mesopotamia, where he lost his life in the unsuccessful attempt to relieve Kut in April, 1916.

Greenhill, R. F., Captain Lancashire Fusiliers, only son of the late Dr. E. F. Greenhill, died of wounds on January 1st. He got his first commission on April 28th, 1915.

Robinson, Richard Bertram, Lieutenant R.N.V.R., youngest son of Dr. R. Holt Robinson, died recently after an operation, aged 44. He was the secretary of the Burnham Yacht Club and of the British Motor-boat Club.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on January 18th, contains a further list of rewards for gallantry and distinguished service in the field. The individual acts of gallantry for which the decorations have been awarded will be announced in the *London Gazette* as early as practicable. The list includes the following medical officers who belong to the R.A.M.C. unless otherwise indicated:

Bar to the Distinguished Service Order.

Temporary Surgeon William James McCracken, D.S.O., M.C., R.N. (D.S.O. gazetted July 18th, 1917).

Distinguished Service Order.

Captain (acting Lieut.-Colonel) Robert Thin C. Robertson.
Captain George V. Davies, A.A.M.C.
Temporary Captains: Archibald S. K. Anderson, M.C., James T. Bowman, Howard B. Graham, Harvey Gordon Young, C.A.M.C.

Second Bar to the Military Cross.

Temporary Captain George D'Rastrik Carr, M.C. (M.C. gazetted February 2nd, 1916, first bar gazetted November 25th, 1916).

Bar to the Military Cross.

Temporary Surgeon James N. McBean Ross, M.C., R.N., attached R.M. (M.C. gazetted July 18th, 1917).

Captains: David MacDonald Steele, M.C., A.A.M.C. (M.C. gazetted November 14th, 1916); Robert Bell Stewart, M.C. (M.C. gazetted January 14th, 1916).

Temporary Captain Francis Ruthven Thornton (M.C. gazetted January 1st, 1917).

Military Cross.

Captains: William F. Abbott, Angus Cameron, Archibald John Collins, A.A.M.C., Joseph Wilfrid Craven, Henry Clarke Davis, C.A.M.C., Eric Macallan Gordon-Glassford, A.A.M.C., Hugh Edward Kirkland, A.A.M.C., Gny Ardlaw Lawrance, A.A.M.C., Alfred J. A. McCabe-Dallas, John Shaw Mackay, A.A.M.C., Philip McRitchie, Melrose Holton Mailer, A.A.M.C., James F. Stewart Marshall, C.A.M.C., Thomas Williamsou Moore, C.A.M.C., Edgar Percival, D.S.O., Henry Frederick Preston, C.A.M.C., William Dempsey Quilty, A.A.M.C., Clive Frederic Robinson, A.A.M.C., Christopher Rogers, John Gray Ronaldson, Walter Hepburn Scott, Ernest C. Whitehouse, C.A.M.C.

Temporary Captains: John Frederick Broughton, Charles Launder Chalk, Henzell Howard Dummere, John Tryweryn Lloyd, James MacGregor, James Murdoch MacKay, David Matthew, Maurice Aloysius Power, Reginald Thompson Raine, Reginald Hernan Tribe.

Temporary Lieutenant (Temporary Captain) William Kealty Campbell, D.S.O.

Temporary Lieutenant Kekhasru Sobraji Master, I.M.S.

The name of Major (temporary Lieut.-Colonel) P. S. Clarke, S.A.M.C., should have been included in the list of officers awarded the D.S.O. in the *London Gazette* of January 1st, 1918, and the necessary correction has now been made in the official records.

The following is a continuation from p. 97 of our last issue of the particulars of acts of conspicuous gallantry and devotion to duty for which the decorations announced in the *BRITISH MEDICAL JOURNAL* of October 6th, 1917, were awarded:

Military Cross.

Captain William Howard Edwin Stewart, R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of a loading post for ambulance cars. His work entailed his being on a road whenever shelling took place there, in order to accelerate the removal of the wounded from that point, and to arrange all possible protection for such wounded as could not be cleared. He personally went to the assistance of four men who had been wounded by a shell and dressed them in the open under heavy fire, setting an admirable example of coolness and devotion to duty under difficult and trying circumstances.

Temporary Captain George Min Adam, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. He carried on with his steady work of dressing and evacuating the wounded in the open under heavy shell fire until his dressing station had to be abandoned owing to its destruction. He then got his cases away safely under most trying conditions and resumed his work at another point, continuing until he was utterly exhausted. He set a splendid example of steadfast courage and devotion to duty.

Temporary Captain Stanley James Annear Beale, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when working in an advanced dressing post. This post was destroyed by a shell which killed the other medical officer and an orderly. Although badly shaken, Captain Beale promptly formed another post and continued to dress the wounded until relieved twenty-four hours later. It was owing to his untiring energy and splendid devotion to duty that many lives were saved.

Temporary Captain Geoffrey Andrew Bird, M.B., R.A.M.C.

A lorry containing ammunition was set on fire about 200 yards from his aid post. Although the road outside was heavily shelled he set a splendid example in personally carrying the wounded from the vicinity of the lorry to his aid post, making the journey under heavy shell fire, and in imminent danger of a sudden explosion of the ammunition, which eventually took place.

Temporary Captain Clarence Albert Brisco, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of bearer parties. After twenty-four hours' continuous work in attending to the wounded without sleep or rest he conducted stretcher parties over ground which was swept by shell and machine-gun fire and almost impassable on account of the mud. He showed a total disregard of his personal danger, both during the attack and for several days afterwards, and by his splendid devotion and gallantry encouraged his men under the worst imaginable conditions.

Temporary Captain William Thomson Brown, M.B., R.A.M.C.

Having gone out with the advanced party of his battalion at 6 a.m., he remained with them until the last party returned at midnight, rendering continuous assistance to the men of his own unit and also to many others wounded on the road. His personal gallantry and utter disregard of danger not only upheld the traditions of his own corps but set a fine example to all ranks of the unit to which he is attached.

Temporary Captain Wilfrid Thomas Chaning-Pearce, R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to wounded men belonging to nine different battalions under heavy and continuous shell fire. His aid post was the only one in the vicinity in such a forward position, and he worked continuously and without rest until all the wounded had been attended to, displaying splendid devotion to duty.

Temporary Captain Francis Bernard Chavasse, R.A.M.C.

During four days of heavy fighting he attended the wounded with untiring energy and exceptional gallantry at very great personal risk. On one occasion, while dressing the wounded in a shell crater under very heavy shell fire, he was hit by bits of shrapnel about the legs and face, but continued to dress each man in his turn and to encourage others who were waiting. On the following day, while dressing the wounded under very heavy shell fire, he was blown over by a shell, but picked himself up and continued his work with the greatest pluck and devotion. He refused medical assistance in both cases, and his indomitable courage was the cause of saving many casualties.

Temporary Captain Victor Lindley Connolly, R.A.M.C.

He led his bearers again and again through barrages of shell fire to attend to the wounded, and it was owing to his splendid courage and personal example that his bearers were kept at work clearing the wounded from a heavily shelled area.

Temporary Captain George Theodore Cregan, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded under heavy shell fire. A few days later, after he had completed his usual round, he volunteered to remain at an advanced dressing station which was short-handed, and worked continually for nineteen hours, treating and evacuating over 700 cases. This gallant and devoted act was performed under continuous and heavy shell fire, during which the dressing station itself was hit. His personal example and disregard of danger has at all times been most marked.

Temporary Captain Douglas St. Clair Creighton, M.D., R.A.M.C.

For conspicuous gallantry and devotion to duty in going forward to most exposed positions to dress and attend wounded, showing a total disregard for his personal safety. After he had cleared a very large area in this manner, he established a first aid post in a forward position, and from there gave great assistance to the wounded of two or three other regiments as well as his own. His gallant conduct and fearless devotion saved the lives of many wounded.

Temporary Captain Eric Payton Dark, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in leading his bearers. He displayed great gallantry and disregard of danger in moving about in the open under the heaviest shell fire, collecting and evacuating the wounded. He worked continuously without a rest for thirty-six hours, by his energy and determination contributing largely to the rapid clearing of the battlefield.

Temporary Captain James Walker Darling, M.B., R.A.M.C.

Throughout a long and tiring day he showed the utmost contempt of danger, his organization of aid posts and stretcher-bearers was beyond all praise, and his tireless energy and devotion in looking after the wounded were the admiration of every officer and non-commissioned officer of the battalion, many of whom specially mentioned him to the commanding officer on account of his gallantry.

Temporary Captain Harold Benjamin Day, R.A.M.C.

He worked night and day for four days with magnificent fearlessness, tending the wounded, not only of his own battalion, but also of all others in the vicinity. At one moment he led a party of stretcher-bearers across the open and brought back fourteen wounded in daylight, in full view of the enemy. This, however, is only one instance of the many heroic acts which this gallant officer performed under heavy shell and machine-gun fire.

Temporary Captain Robert Stuart Gibson, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty during an intense hostile bombardment. He crossed the ground where very heavy shells were continuously bursting, and remained in a battery position attending the wounded under heavy fire and at great risk to himself. He displayed magnificent fearlessness and devotion to duty.

Temporary Captain John Charles Bollean Grant, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty during an attack. Finding that all his stretcher-bearers were occupied he went forward and dressed the cases himself on the spot, sending them back as opportunity arose and stretchers turned up. By this gallant act of devotion he undoubtedly expedited the evacuation of the wounded from the shelled area.

Temporary Captain Norman Grellier, R.A.M.C.

For conspicuous gallantry and devotion to duty during an attack. A shell came through the door of his aid post, killing his sergeant and several other men; he himself was knocked over and severely shaken by the concussion. In spite of this, however, he carried on his work unaided, and remained at his post under continual hostile shell fire, setting a magnificent example of devotion and fearlessness.

Temporary Captain Frederick Harris, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in working for three hours in the open under intense hostile bombardment, during which time he succeeded in getting many of the wounded under cover, and undoubtedly saved many lives. His coolness and fearless devotion were beyond all praise.

Temporary Captain Howard Havelock Hepburn, M.D., R.A.M.C.

For conspicuous gallantry and devotion to duty in accompanying his brigade into a forward position, where he attended to the wounded under very heavy shell fire, and remained with the guns until they withdrew. By his coolness and courage he greatly inspired all the detachments, and carried out his work with utter disregard of personal safety throughout the day. But for his great gallantry, under most difficult conditions, many more lives would have been lost.

Temporary Captain James Hill, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in working unceasingly for forty hours evacuating wounded and continually going over ground which was under heavy shell fire. He showed great zeal and splendid fearlessness in his work, by his personal example earning the admiration of all ranks.

Temporary Captain Archibald Forbes Laird, M.D., R.A.M.C.

He established his aid post in a farm and attended the wounded for three days, although under constant shell fire, which at times became intense. He was slightly wounded in three places, but his gallantry and devotion to duty were the cause of saving many casualties.

Temporary Captain George Edwin Lindsay, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty. In addition to dressing over 600 cases at his aid post, he made repeated journeys to the front line under heavy fire, seeking for and collecting wounded. He carried one wounded man off the field on his back through rifle, machine-gun, and shell fire, and when he had finally got all our own wounded back he made another journey into the front line to try to rescue some of the wounded enemy in front of our lines. By his coolness, daring, and unselfish disregard of personal danger he saved many lives.

Temporary Captain Jerome Ivo O'Sullivan, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of bearers. In conjunction with another officer he personally supervised the collection of many wounded in front of our lines and got them into dug-outs in our front line. He then conducted his bearers himself round these dug-outs, continuing to do so until all the cases had been cleared. During the subsequent operations he repeatedly led his bearers through heavy barrages, inspiring them with such enthusiasm by his own personal courage that the evacuation of all the wounded was successfully carried out.

Temporary Captain Clement Rickard MacLeod, R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. In the face of extreme hostile shelling he led stretcher-bearers, collecting the wounded and gassed cases, and throughout a period of twenty-four hours displaying a coolness and gallantry which directly influenced the saving of many lives.

Temporary Captain Daniel McVicker, R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded. He was three times wounded on the same day, but although in great pain he continued to carry on until completely exhausted and unable to go any further, when he was ordered back to the dressing station. His pluck and devotion to duty were beyond all praise.

Temporary Captain William Hilton Parry, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when in command of a bearer division. He led his bearer squads through shell fire with great fearlessness and devotion, in order to collect the wounded, and worked without a rest for thirty-six hours, dressing and evacuating wounded from the front line under the most trying conditions.

Temporary Captain James Alexander Paterson, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty when the rear of his battalion was heavily shelled on the line of march. Under an intense hostile bombardment he hastened to the spot, dressed the wounded, and cleared them from the road, personally seeing to their removal to the aid post. He then returned and cleared the dead from the road, setting a fine example of coolness and disregard of danger.

Temporary Captain Frederick Tavinor Rees, R.A.M.C.

For conspicuous gallantry and devotion to duty when in command of bearer divisions. He displayed tireless energy in making preparations for the attack, and during the operations carried out his duties with splendid devotion, frequently working under difficult and dangerous conditions. Early in the action he went forward under fire and made a thorough personal reconnaissance over difficult ground, thereby facilitating the clearance of the wounded.

Temporary Captain Douglas Swan Robertson, M.B., R.A.M.C.

Although slightly gassed on the evening before an attack, he carried on throughout the whole of the following day and night, attending to the wounded in the open under heavy shell fire with a splendid disregard of personal danger, although nearly all his stretcher-bearers were killed or wounded around him. Two days later he helped to dig out a man who had been buried by a shell, working the whole time under heavy shell fire. He was slightly wounded, but remained with his battalion.

Temporary Captain Alexander Hugh Dickson Smith, R.A.M.C.

During a heavy hostile bombardment of a battery position a gunner was severely wounded and buried by a shell. Captain Smith came over from the next battery position, and, with the assistance of a gunner, helped to extricate the wounded man and dress him where he lay. The enemy's fire continued throughout, one shell falling a few yards away and wounding the gunner. In spite of this, however, the dressing was completed and the wounded man safely removed.

Temporary Captain James Anstruther Smith, M.B., R.A.M.C.

During an advance he worked with unflinching energy, collecting and dressing the wounded under heavy fire in the open. By his great personal courage and devotion to duty he cheered all ranks and undoubtedly saved many lives.

Temporary Captain Thomas James Logan Thompson, M.B., R.A.M.C., attached K.O.S.B.

He established an aid post, where he worked continually at the evacuation of the wounded, although under heavy shell fire and in the open for most of the day. He was very cool and wonderfully cheerful during the whole time, especially under particularly heavy shell fire during the night, by his splendid example inspiring the wounded with the greatest confidence.

Temporary Captain Edward Archibald Walker, M.D., R.A.M.C.

For conspicuous gallantry and devotion to duty in continually leading his stretcher-bearers through heavy barrage and successfully bringing back wounded under heavy shell fire.

Temporary Captain Hubert Francis Wilson, M.B., R.A.M.C.

He repeatedly led stretcher-bearers under heavy fire, and succeeded in evacuating all the wounded on his front; and when most of the stretcher-bearers had become casualties he organized a party of riflemen, with whom he worked for eight hours in the open under shell fire, and continued to clear many wounded. He then returned and led up another large party, with which he succeeded in clearing the front, having displayed splendid courage and devotion to duty throughout the day.

Temporary Lieutenant Gerald Woodforde Harrison, R.A.M.C.

For conspicuous gallantry and devotion to duty during an attack. His aid post being blown up, he worked in the open, dressing the wounded, moving freely about under heavy shell fire, and by his great personal exertions and complete disregard of danger, under very trying circumstances, he was instrumental in saving the lives of many men.

Temporary Lieutenant Reginald Gordon Hill, M.B., R.A.M.C.

During an attack he continually attended to wounded under a heavy barrage, and, on the objective being gained, he quickly formed a dressing station, where he was indefatigable in his attention to the wounded of his own and another battalion, although under continuous fire for two days. By his cheerfulness and splendid devotion to duty he set a fine example to all ranks.

Temporary Lieutenant William Johnstone Isbister, M.B., R.A.M.C.

During the attack and capture of a position he displayed complete disregard of danger in attending to the wounded and evacuating them under heavy shell fire. During this work, all of which was done under great difficulty and practically in the open, he was once partly buried, but completed his dressing of the wounded, setting a splendid example of devotion to all.

Temporary Lieutenant Ronald Sinclair Kennedy, R.A.M.C.

For conspicuous gallantry and devotion to duty in dressing and attending to wounded men under extremely heavy shell fire. At great risk of his life he made several journeys to the front line, and personally brought in wounded men who otherwise must have been killed by the intense hostile barrage.

Temporary Lieutenant Peter Ryan, R.A.M.C.

When heavy casualties were occurring in the batteries he showed complete disregard of danger in going out into the open for the wounded, rescuing those who were buried, and dressing the wounded. During the whole time heavy shells were falling close by, and on two occasions he was knocked down by these and by exploding ammunition dumps.

Temporary Lieutenant Thomas Charles Dalrymple Watt, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty under exceptionally difficult and trying circumstances. Owing to continual rain and heavy shelling, no trenches were available, and the men had to be distributed amongst shell holes, the regimental aid post being in the open. He attended to the wounded unceasingly all day under continuous shell fire, repeatedly going through heavy fire to administer first aid. Owing to the mud, many of the men would undoubtedly have been drowned but for his prompt assistance, and it was due to his splendid organization and devotion to duty that all the wounded were evacuated by the evening.

MENTIONED IN DISPATCHES.

A Supplement to the *London Gazette*, issued on January 16th, contains a list of names brought to the notice of the Secretary of State for War by General Sir Edmund Allenby, Commanding-in-Chief Egyptian Expeditionary Force, for distinguished services in connexion with military operations under his command. The following medical officers are included in the list:

Staff.

Colonel (temporary Surgeon-General) J. Maher, C.B., A.M.S.
Lieut.-Colonels (temporary Colonels): E. B. Dowsett, R.A.M.C., A. H. Tubby, C.M.G., M.B., F.R.C.S., A.M.S.
Major (temporary Lieut.-Colonel) H. Richardson, M.D., R.A.M.C.
Majors: C. E. Hercus, M.B., N.Z.M.C., P. S. Lelean, C.B., F.R.C.S., R.A.M.C.

Royal Army Medical Corps.

Lieut.-Colonels: A. C. Goodwin, M.B., F.R.C.S., H. W. Thomson, M.D.
Majors (temporary Lieut.-Colonels): J. W. Bird, D.S.O., J. M. G. Bremner, M.B.
Majors (acting Lieut.-Colonels): A. Leggat, M.B., J. W. Leitch, M.B.
Major F. Gracie, M.B.
Captain (acting Lieut.-Colonel) T. B. Layton, M.D.
Captains: F. Alcock, M.D., E. C. Crichton, M.B., E. P. Minett, A. R. Muir, M.B., R. P. Starkie (S.R.), I. D. Stubbs.
Temporary Captains: M. Bates, M.B., F.R.C.S., C. I. Hannigan, M.B., W. Leggett, M.D., R. M. Wright, M.B.
Temporary Quartermaster and honorary Lieutenant F. L. Harsant.

Australian Army Medical Corps.
Captains J. F. G. Fitzhardinge, H. Sutton.

Indian Subordinate Medical Department.
First Class Subassistant Surgeon Abdul Majid.

The list also contains the names of twenty-four warrant and non-commissioned officers and privates of the R.A.M.C. and four of the A.A.M.C.

England and Wales.

PHYSICAL TRAINING IN SECONDARY SCHOOLS IN WALES.

THE Welsh Department of the Board of Education has issued a hortatory memorandum to educational authorities in Wales on the neglect of physical training in secondary schools in the principality. There is one paragraph indeed which is distinctly minatory, for it informs all the authorities that no school can henceforth be regarded as efficient unless it makes proper arrangements for the physical training in every school of all pupils fit to receive it, or is at least doing all in its power in this direction. The Welsh Department of the Board of Education is a little whimsical in its requirements, inasmuch as it will not accept military drill and insists upon the schools building gymnasiums. A scheme of physical training in a secondary school should include (a) a suitable plan for physical exercises, comprising (1) formal gymnastics on the line of the Swedish system; (2) dancing "suitable for use in schools"; and (3) playground and field games, swimming, etc.; (b) fully qualified teachers of gymnastics; (c) a room or gymnasium containing at least a minimum of Swedish apparatus; (d) arrangements for not less than three lessons a week in formal gymnastics (including team games, dancing, etc.) of thirty to forty-five minutes in duration, according to the age of the pupils. It does not hope at once to attain this ideal, but requires every school to comply with two conditions—namely, that physical training should always be in the hands of a teacher who has had some special training on modern lines, and a minimum of two lessons a week of half an hour's duration, given at a period of the day favourable to the teaching and performing of physical exercises. The supply of expert teachers being limited, the Board is prepared to accept as physical trainer the ordinary class teacher who has received some special training. It urges that greater facilities should be afforded to teachers to improve their qualifications by taking the summer or vacation course of instruction in physical exercises officially recognized by the Board of Education, which for the last two or three years has granted allowances to selected teachers to enable them to attend such courses. The allowances have been travelling expenses and £1 a week for maintenance! The Board's grants, however, are limited, not only in amount but in number, and it urges local education authorities to "be liberal in offering similar inducements to teachers to undertake this training." It also advises that it would be advantageous to allow the organizer of physical training, where appointed, to exercise general supervision over the secondary and technical schools as well as over the public elementary schools. It is pointed out that an urban authority may adopt the Museums and Gymnasiums Act, 1891, under which it can provide a gymnasium and establish classes and grant the exclusive use to any person or body of persons for two hours a day for gymnastic exercises on conditions as to payment, and so on, as may be arranged. The Board is prepared to consider applications for grants under Article 44 of the new Regulations for Secondary Schools in Wales, to enable visits to be paid by teachers of physical training to a school chosen as specially suitable, and expresses the expectation that school governors will avail themselves of the opportunity created by the payment of increased grants to secondary schools to place the teaching of physical exercises on a far higher plane than it occupies at present in Wales, and in particular to appoint well-qualified and adequately remunerated teachers of the subject. The document does not seem to disclose much foresight or insight. The insistence on gymnasiums appears to be an example of the Germanization prevalent before the German war among Government officials. Might not the Secretary have found better employment for his own time and the depleted stock of printing paper?

THE LIVERPOOL MEDICAL INSTITUTION.

At the annual meeting of the Liverpool Medical Institution on January 17th it was stated that the total membership is now 392 as against 386 at the beginning of 1917. The financial statement, in spite of the fact that no subscriptions have been demanded from members on active service, showed a credit balance, due to various economies by which expenditure has been diminished. As a result of the biennial election Mr. William Thelwall Thomas, M.Ch. Liverpool, F.R.C.S., Honorary Surgeon to the Liverpool Royal Infirmary, was unanimously elected President; Mr. D. Douglas-Crawford, Mr. G. S. Stansfield, Mr. K. W. Monsarrat, and Dr. Llewellyn Morgan were elected Vice-Presidents; Mr. C. Thurstan Holland, Treasurer; Dr. Hubert Armstrong, General Secretary; Dr. Walter Oram, Secretary of Ordinary Meetings, Mr. T. C. Litler-Jones, Secretary-elect; Dr. J. Martin Beattie, Secretary of Pathological Meetings, Dr. H. Leith Murray, Secretary-elect; and Dr. R. W. Mackenna, Librarian and editor of the *Liverpool Medico-Chirurgical Journal*. The customary vote of thanks was passed to the retiring officers.

CENTRAL MIDWIVES BOARD.

The Board held penal sessions on January 9th and 10th, Sir Francis Champneys presiding. Eleven cases were decided, and of the women cited to appear five were struck off the roll. The most frequent charge was that of not obtaining medical aid for ophthalmia neonatorum. Inability to take the pulse and temperature and technical breaches of the rules also figured largely.

At the ordinary monthly meeting on January 10th the Standing Committee reported a letter from the Child Welfare Inquiry Office, asking the Board to appoint a representative to attend a national conference to be held on February 14th to consider a scheme adopted by the Child Welfare Council recommending changes in the law with regard to unmarried mothers and illegitimate children. The Board decided to appoint Mrs. Salter as its representative. With reference to a letter from the Deputy Medical Secretary of the British Medical Association calling the attention of the Board to an advertisement by a midwife offering to attend patients at their own homes for "twilight sleep" treatment, it was decided that the midwife should be cited to appear before the Board. Eight women were removed from the roll on their own application.

A MINISTRY OF HEALTH.

On January 17th the executive of the Urban District Councils Association, at the Central Hall, Westminster, recorded its opinion that the Local Government Board should be recognized as the Ministry of Public Health, that the creation of a new Ministry would be undesirable on economic grounds and disastrous to the efficient working of the public health services, and that it was essential that the local administration of public health matters should remain in the hands of local authorities. Three representatives were appointed to discuss the matter with Dr. Addison (Minister of Reconstruction).

Scotland.

MOTHER WELL.

THE Carnegie United Kingdom Trust has determined, as a result of its inquiry into the physical conditions of mothers and children in the United Kingdom, to assist in the establishment of model welfare schemes in certain urban centres. It has selected Motherwell, in Lanarkshire, as the town in which to make the first experiment in Scotland. Motherwell has a population of 40,000, and is the centre of a district which includes Bothwell, about three miles nearer Glasgow, engaged in coal-mining and in iron and engineering works. The Town Council of Motherwell has accepted the offer of the trustees to meet the cost of erection and equipment of a building, provided the council supplies a suitable site; that the plans and estimates to be drawn up by the council shall be approved by the trustees; that the council will maintain the welfare centre by means of Government grants and local rates and contributions; that the scheme is made part of a local comprehensive system of physical welfare approved by the Local Government Board for the purpose of imperial grants; and that the council shall make reports on the work of the centre to

the trustees, to be embodied in their annual reports. The town council, after accepting the offer, instructed the Public Health Committee to frame a scheme. A punning correspondent suggests that the scheme should serve to keep the mothers well in Motherwell and the mothers and infants both well in Bothwell.

DISABLED SOLDIERS.

At a meeting on January 12th of the Joint Institutional Committee for Scotland, consisting of representatives of the Scottish Joint Disablement Committees, the Red Cross Society, and the War Office, when Sir A. Griffith-Boscawen, Parliamentary Secretary to the Ministry of Pensions, was in the chair, it was reported that the neurasthenic home of recovery at Craigend, Liberton, Edinburgh, would probably be ready at the end of February, and that the epileptic colony at Murieston, Mid-Calder, would be opened in the course of a few days. It was also reported that the Red Cross Society would place a number of small auxiliary hospitals no longer required by the military authorities at the disposal of the Committee for use as convalescent homes. The erection of a sanatorium for consumption at Stornoway was approved and plans were considered for extending the Springfield colony at Polton. A combined hospital and hostel is to be established at Aberdeen to which men can be transferred for the three weeks immediately preceding their discharge from the army. It was stated that the difficulties of the Committee would be considerably increased by a recent order of the War Office forbidding the readmission of discharged men to military hospitals for in-patient treatment. The Scottish section of the Committee, appointed by the Ministry of Pensions to consider the adequacy of hospital accommodation and facilities for treatment both for discharged men and the civil population throughout Great Britain, has held a meeting in Edinburgh, when it was decided to assist the Scottish Insurance Commission in completing the information already in its possession with regard to hospital accommodation, facilities for nursing, and other matters in connexion with treatment before proceeding to any independent inquiry. The Scottish section of the Committee consists of Sir A. Griffith-Boscawen (chairman), Sir Donald MacAlister, Dr. J. C. McVail (Scottish Insurance Commission), Dr. Leslie Mackenzie (Local Government Board), and Sir John Macaulay.

Ireland.

NATIONAL HEALTH INSURANCE IN IRELAND.

The report on the administration of National Insurance during the years 1914-1917 contains, as was stated last week, a section on Ireland. As the result of a circular deprecating during the continuance of the war transfers from one society to another, save in exceptional circumstances, a great and continuous decrease in the numbers has occurred. During the half year before this circular was sent out there were 2,464 such applications for transfer, but in the following six months only 379. A small proportion of the Irish societies, mostly those of small membership, have experienced deficiencies in their administrative accounts. For the period ended January 11th, 1914, there were twenty-six deficiencies, for the period ended December 31st, 1914, there were sixteen, and for the following year thirteen. In twelve cases the deficiencies were small and were carried forward, as permitted by the regulations. The great majority of the remaining deficiencies have been, or are being, made good by other means than levy. The number of approved societies operating in Ireland on December 31st, 1916 was 223; of these 213 were centralized societies, and 10 societies with branches. Immediately preceding the outbreak of war there were in Ireland 716,318 insured persons, 480,028 men and 236,290 women. The total contribution of Irish approved societies towards the financing of the war by investment in war securities of moneys arising through the National Insurance Acts may be taken at approximately £400,000, apart from the National Insurance moneys invested in those securities by the National Debt Commissioners.

Of the thirty-nine Insurance Committee areas in Ireland, the County Councils of thirty have appointed a tuberculosis

officer, and either a partial or a complete scheme for the prevention, detection, and treatment of tuberculosis is in operation. Comprehensive agreements have been entered into between the insurance committee and the council in twenty-two of these areas, and it is hoped that, as a result of negotiations now proceeding, agreements will shortly be completed in five other areas. In eight areas the councils have not yet formulated any schemes for the treatment of tuberculosis. In one area a scheme which was in operation has been abandoned, but on the whole the agreements have so far proved very successful. The number of beds available for the treatment of tuberculous cases in sanatoriums has increased considerably, but further accommodation is necessary if sanatorium treatment is to be provided promptly in each case. The accommodation in institutes for the treatment of advanced cases is still very inadequate, and the position in this respect has been rendered worse in consequence of the war. No change has been made since the last report in the condition governing the provision of domiciliary treatment, but the difficulties existing in certain areas, as regards the fees payable to the medical profession, have, it is stated, to a large extent been removed. As a result of their experience since the commencement of the Insurance Act, the Commissioners are of the opinion that no really satisfactory progress in dealing with the problem of tuberculosis is possible until all forms have been made compulsorily notifiable. There is no doubt that through absence of compulsory notification, application for treatment is, as a rule, made only at a stage of the disease when either a prolonged and costly course of treatment is necessary with uncertain results, or the disease is so advanced that expenditure on treatment cannot be productive of any lasting results.

At present there are 1,412 medical certifiers in Ireland. The new scheme of certification, it is said, has proved a considerable improvement upon the conditions which obtained previous to its coming into operation.

As medical benefit is not available in Ireland, the scheme of benefits for exempt persons differs from that in operation in Great Britain; the qualifications for sanatorium benefit are slightly different, and in lieu of medical benefit a sickness benefit of 6s. a week, commencing from the seventh day of illness, is provided.

IRISH COUNTIES WAR HOSPITAL.

At a meeting of the executive committee of the Irish Counties War Hospital, Lieut.-Colonel Pringle, F.R.C.S.I., submitted statistics for the first six months, showing that 817 men had been admitted, of whom 631 had been discharged and 186 remained under treatment. Of the 631 men discharged, no fewer than 146, or about 25 per cent., have been returned to their regiments for service, and 131 sent to command depôts or a military convalescent hospital, all of whom would probably be able to rejoin their units in less than three months; it thus appeared that 43 per cent. of the patients discharged were able to rejoin the colours either immediately or in the near future. Of the remainder, two died, ten were discharged from the service, and the balance either transferred to other primary hospitals (generally for the purpose of being nearer their homes), to auxiliary convalescent hospitals, or to special hospitals (mental, infectious cases, etc.). A meeting of the general committee will be called at an early date, when a half-yearly report prepared by the finance committee will be presented.

IRISH TUBERCULOSIS MEDICAL ASSOCIATION.

A meeting of the members of the Irish Tuberculosis Medical Association was held in Dublin last week. Dr. A. H. Hanley was elected president, Dr. Gillespie and Dr. Cuffe vice-presidents, Dr. Quinlan honorary secretary, and Dr. Timoney honorary treasurer. In the discussion which took place stress was laid on the importance of bringing cases to the notice of the tuberculosis medical officer in an early stage, as at that stage cases invariably yielded good results. It was recommended that opportunities should be given to medical students for seeing cases of disease in an early stage with the tuberculosis medical officer, and that lectures on the early diagnosis of tuberculosis should form part of the curriculum. It was also advised that the time spent by nurse probationers in sanatoriums should count as part of their general training.

A deputation was appointed to wait on the Local Government Board, to discuss, among other matters, the necessity of standardizing the records for all countries.

NORTH DUBLIN UNION.

The guardians of the North Dublin Union are discussing the diet in the nursing ward in connexion with the occurrence of six cases of typhoid fever. Dublin itself is said to be peculiarly free from epidemics, and it is thought that the cases in the nursing ward may be connected with the alleged habit of some of the women of keeping unused food in the washhouse or lavatory. The women appear to have objected to the soup given to them, and Dr. Flood, the Local Government Board inspector, has expressed the opinion that the diet is insufficient for nursing mothers who are working in the laundry. The board of guardians has called for a further report, and meanwhile has resolved to accept Dr. Flood's recommendation that the nurseries should be moved.

Canada.

THE MILITARY HOSPITALS COMMISSION.

THE Military Hospitals Commission, which is charged with full powers in connexion with returned soldiers, had about 11,000 men in its institutions last November, and it was expected that the number would be increased to 15,000 before the end of the year. It has been difficult to arrange for adequate medical and surgical treatment, owing to the fact that so large a proportion of the medical men of Canada have placed their services freely at the disposal of the military authorities, that so many are now serving at and near the front, and that great progress has been made in the treatment of men wounded or invalided in the war. An arrangement has now been reached with the Department of Militia and Defence by which the medical services in the institutions of the Commission shall be performed by the Army Medical Corps of the Department of Militia and Defence. Lieut.-Colonel Alfred Thompson, M.P., medical superintendent of the Commission, has received a staff appointment as Assistant-Director of Medical Services (Invalids). He will, under the Director-General of Medical Services (Surgeon-General Fotheringham, C.M.G.), carry on this work with a staff selected from the Army Medical Corps. The Militia Department will make arrangements by which the present medical staff can be retained. The office of Lieut.-Colonel Thompson as A.D.M.S., Invalids, will continue to be at the head quarters of the Military Hospitals Commission. There will thus be linked together, in caring for those invalids, the Military Hospitals Commission and the Army Medical Service Corps.

PUBLIC HEALTH IN CANADA.

The number of rejections among recruits on account of physical unfitness since the beginning of the war has awakened the general public to the importance of hygiene and preventive measures against disease. There is a general feeling that the remedy lies in the co-ordination of efforts directed towards the conservation of health, and there is a movement towards the establishment of a Federal Bureau, or, failing that, Provincial Departments of Public Health. The establishment of a Federal Bureau of Health has long been advocated by the medical profession, and, of late, resolutions have been passed by various bodies in Alberta and other provinces in favour of the creation of a provincial department. In the province of New Brunswick Mr. John Hall, a graduate of the Massachusetts Institute of Technology, has been appointed to make a survey of health and sanitary conditions in the province as a preliminary step towards the establishment of a health department as a branch of the provincial government.

THE trustees of the Rockefeller Foundation in announcing their budget for 1918 state that possibly more than £2,000,000 will be spent in public welfare work, half of which will be used for war relief. If necessary, the Foundation can draw on an available fund for a further million for this purpose. A sum of £215,400 will be applied to the combating of hookworm, yellow fever, and other scourges. Appropriations to the amount of £83,000 are made for the Tuberculosis Commission in France.

Correspondence.

DEFECTS IN THE LUNACY LAWS.

SIR,—The treatment of shell shock and other mental cases arising from the war has accentuated the necessity for amendment of the existing lunacy laws.

A Select Committee of the Medico-Psychological Association is now sitting to consider the best method for securing the legal changes which have been long overdue in this direction. The Committee invites information from medical men and others intimating their experience of the defects in the present system of lunacy laws and administration, and indicating what legislative alterations are in their opinion desirable.

Communications should be sent to the Secretary of the Committee at 10, Chandos Street, Cavendish Square, W. 1. —We are, etc.,

H. WOLSELEY-LEWIS, M.D., F.R.C.S.,

Chairman.

R. H. COLE, M.D., F.R.C.P.,

Secretary.

January 19th.

THE PULSE PRESSURE TEST BEFORE OPERATIONS.

SIR,—Your reviewer of Cashman's work on the above subject has taken very meekly Sir James Mackenzie's rebuff, and humbly bows down under the weight of such an authority. Sir James Mackenzie's facts, when he has got any to state, are of value; but, apart from facts, his opinion should carry no more weight than that of any one else; in fact, I am inclined to think that a few such letters, based neither on facts nor on a knowledge of the subject, will diminish his prestige as a heart specialist. "Beyond supplying the force that causes the blood pressure the heart takes little part in the variations that occur." Apart from such a force no arterial pressure could be maintained, and when the force-pump ceased to act the arterial pressure would fall to zero in a second or two required to expend the energy stored up in the arterial walls. "The factors concerned in regulating the changes in blood pressure are so obscure that observations drawn from them are little better than guesswork." If this be really the matured opinion of Sir James Mackenzie then the sooner he tries to clarify the obscurity the better. An American recently stated facetiously that in the present day there are many observations, wise and otherwise, mostly otherwise. I am afraid Sir James Mackenzie's observation belongs to the latter class. If he would devote a little time, if he have any to spare, to a study of the actions of the secretions of the ductless glands, a good deal of the haziness which at present seems to obscure his mental vision might vanish. If he had paid some attention to my observations on the effects of hyperthyroidism on the soldier's heart he might not have fallen over head and ears into that pitfall laid for him with the "heart pills."

The great value in Cashman's work is not in the mere statement of the pulse pressure but in the variations which occur in that pressure under exercise and change of posture. Personally I do not care for a mere statement of pulse pressure as a separate entity apart from the diastolic and systolic pressures. A pulse pressure of 50 between a diastolic pressure of 100 and a systolic pressure of 150 mm. of mercury shows a much better pulse than one of a pressure of 100 between 150 and 250. In aortic regurgitation there is often an enormous pulse pressure, but this is not the kind of heart which one would deliberately select as specially suited for an anaesthetic. A glass of whisky and hot water will at least temporarily raise the pulse pressure in most individuals, but this is not the kind of drug which one would select to improve the staying power of the heart.

In conclusion, I wish to subscribe to the value of Cashman's observations, and will reserve any further remarks on the subject for a future occasion.—I am, etc.,

Liverpool, Jan. 20th.

JAMES BARR.

PRIMARY EXCISION OF GUNSHOT WOUNDS OF THE ELBOW-JOINT.

SIR,—Mr. Fagge (January 5th, p. 36) very correctly criticizes the term "primary" which I used in speaking of an early operation in distinction to a late or secondary

operation when healing has occurred and ankylosis has resulted from the sepsis in the joint. I agree with him that the word "primary" should be reserved for those cases which are operated upon in the casualty clearing stations in the first few hours after the infliction of the wound. My recent experience in the casualty clearing stations in France has impressed me with the great efficiency of the surgery carried out there, more especially in the early treatment of wounds, and has still the more impressed me with the fact that if, in suitable cases, excision of the elbow-joint were performed after thorough removal of the wound and infected tissue and the incisions closed, the results obtained would be much better than if operation be performed when sepsis has become established.

The choice of a case suitable for excision depends chiefly upon the local conditions. Doubtless the removal of a small attached piece of articular surface is enough in slight injuries, but where the whole articular surfaces are much comminuted and the fracture lines do not spread too far into the shaft of the humerus. I consider that an immediate excision of the joint would give the best result, for, as Mr. Fagge points out, there is a greater probability of restriction of movement by callus formation about the joint than that a free removal will result in a flail joint. Hence a careful selection on the part of the surgeon is necessary before excision is undertaken.

Mr. Hey Groves would limit early operative treatment to the removal of detached fragments of bone, and suggests that in septic cases drainage of the elbow-joint can be obtained by division of the base of the olecranon, with subsequent reattachment to the ulna. I tried this method quite early in three cases, but abandoned it because I was unable to control the sepsis by it. At the same time the results obtained by excision in the presence of sepsis in the joint have been such that I would not hesitate to repeat it when similar suitable cases are encountered.

Mr. Hey Groves remarks that the olecranon should always be preserved if possible so as to retain the action of the triceps. This can equally well be obtained by reflecting the triceps with the periosteum of the olecranon on each side by a median posterior incision.—I am, etc.,

London, Jan. 21st.

R. H. JOCELYN SWAN.

VACCINES IN SKIN DISEASES.

SIR,—With reference to Dr. Adamson's very interesting paper in your issue of January 5th concerning the treatment of sycosis, impetigo and furunculosis, may I comment upon one or two of his statements from a bacteriological point of view?

At the outset Dr. Adamson states that "considerable numbers of able-bodied men become invalided [presumably he speaks in a military sense] on account of the chronic staphylococcal infections of the skin" aforementioned. That the incidence of such complaints is considerable no military doctor will deny, but I must confess that these complaints, judging from such cases as I have seen in the last 2½ years, have seldom, if ever, led to invaliding from the army—for this reason, that where I have worked we have managed to cure such cases. At this hospital I have had sent to me within the last six months only nine cases of intractable sycosis, but the incidence may be greater elsewhere. One case was treated with medicaments for six weeks and his sycosis became worse and involved beard, ears, and right wrist (impetigo-sycosis). He then came to me and had an autogenous vaccine and no other kind of treatment whatever. He began with a dose of 200 million and ended, completely cured, without any reaction to speak of, at the end of three months, with a dose of 2,000 million (*Staphylococcus aureus*). There was no relapse. The man is an orderly still working here. The other eight cases were cured more swiftly. Amenable cases are cured by the physicians and many do not reach me. As regards chronic furunculosis, I have on record a recent series of 77 consecutive completed cases. All are cured save one who was at first treated with stock vaccines, and these having failed to cure within a reasonable time he now receives an autogenous vaccine and is rapidly improving, that is, he has a smaller and only an occasional boil. Shortly he will be clear.

Dr. Adamson says in relation to furunculosis—and I

think somewhat unjustly—that "the once much-vaunted treatment by vaccines has not proved the panacea it was proclaimed." Given autogenous vaccines in every case, I beg to differ. I am treating 30 to 40 skin cases per week therapeutically with vaccines in a hospital of 1,000 beds. The majority of these are skin cases. Surely there must be something in all this? With reference to chronic impetigo of the trunk, not many cases have come my way. I do not think we get many, but I have treated six cases of a pure streptococcal pyoderma with vaccines, and have obtained a full percentage of cures. I am not aware that this condition is ever converted into anything else bacteriologically.

I am sure that the reason why vaccines often fail is because the fact of germ specificity is not sufficiently recognized. The immunizing powers of a stock vaccine may be sufficient for prophylaxis, as in typhoid (and sometimes not completely so even then), but it is rare that they possess sufficient immunizing powers to be therapeutic. Commercial vaccines may be stale. Most therapeutic vaccines are stale after three months, especially those of the coli-typhoid group, as Emery and Allen have pointed out. Hence, if one fails to get cures with small doses such as Dr. Adamson uses in furunculosis and of stock vaccines, personally I for one am not surprised that he is disappointed. But why blame vaccine therapy?

I beg to thank Colonel Sir W. R. Crooke-Lawless, M.D., C.B.E., C.I.E., for permission to publish these results.—I am, etc.,

A. GEOFFREY SHEPA, B.A., M.D., B.C. Cantab.,
Hon. Captain R.A.M.C.

Pathological Laboratory,
British Red Cross Hospital, Netley,
January 15th.

THE CAUSATION OF SEX IN MAN.

SIR,—The review in the JOURNAL of January 5th (p. 18) of Dr. Rumley Dawson's book reminds me of a case in which some years ago I operated on a lady married for seven years without children, who now had a tubal pregnancy on the left side. I was compelled to remove the ovary on that side with the tube. Afterwards she wrote to me that she had a healthy daughter, followed in due course by another, and then by a healthy son. I think this makes it plain that the theory of each ovary being responsible for the one sex cannot be true.—I am, etc.,

Lurgan, Ireland, Jan. 16th.

J. SINGLETON DARLING, M.D.

SIR.—The review of Dr. Dawson's book states that he claims that ova from the right ovary produce males, and ova from the left ovary females. The following facts in my own experience are against Dr. Dawson's theory: On July 5th, 1908, I assisted in the removal of the right ovary of Mrs. — at the Warrington Infirmary for a cystic tumour with twisted pedicle. Since then she has had three children, two boys and one girl. The ova concerned, I presume, came from the left ovary, for the possibility of ovarian tissue being included in the stump of the pedicle in this case may be wholly discounted.—I am, etc.,

Warrington, Jan. 21st.

J. S. MANSON.

SHOULD NON-WORKERS HIBERNATE?

SIR,—Should non-workers hibernate? Yes, in a modified sense! The food we consume is chiefly spent in producing and maintaining animal heat, physical and mental energies. Roughly, five-sixths of food values go to the former and one-sixth to the two latter. Of every 100 calories of heat produced within the body 80.1 per cent. is lost by radiation and conduction; 14.7 per cent. by evaporation; 2.6 per cent. in heating food and drink consumed, and 2.6 per cent. in heating inspired air.

Rest in bed till late in the day, a modified hibernation in fact, will clearly reduce our heat loss and output of energy, with consequent reduced food requirements. I therefore most strongly urge that non-workers—the idle poor, and rich, the huge population of infirm and insane persons, be encouraged, nay, be compelled, to remain in bed, warm and at rest, till noon daily.—I am, etc.,

Bournemouth, Jan. 21st.

W. JOHNSON SMYTH, M.D.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS.

The following subscriptions to the Fund have been received during the week ending Wednesday, January 23rd:

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

Universities and Colleges.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—*Surgery*: H. Miller, *Midwifery*: H. Miller, E. Spence. *Medical Jurisprudence*: J. J. van Niekerk, J. M. Speirs, L. L. Steele, W. B. Watson, B. Chieftiz, V. A. Rankin, A. Galustian, J. C. Meek, J. K. Steel, S. A. Faulkner.

The following candidates having passed the Final Examination have received the diplomas of L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:

W. O'G. Donohue, C. R. C. Moon, Arukatti Patabendigo Frederick Abeyuriya.

Obituary.

HAROLD FREDERIC MOLE, F.R.C.S.,

SURGEON TO THE BRISTOL ROYAL INFIRMARY.

MR. HAROLD F. MOLE, F.R.C.S., died at his residence, 24, College Road, Clifton, on December 21st, 1917, from heart failure following asthma, to which he had been subject since childhood. For many years his brilliant professional career had been seriously handicapped by ill health, but he never allowed this to interfere with the excellence of any work he undertook.

After studying at the Bristol Medical School and Royal Infirmary, where he was awarded the Tibbits Memorial Prize for practical surgery, he took the diplomas of L.R.C.P., M.R.C.S. in 1890, and that of F.R.C.S. in 1892. In 1891, after holding junior appointments at the Royal Infirmary, he became curator of the museum, the post being created by the staff in order to retain him as a colleague. From 1895 to 1902 he was in turn house-physician, house-surgeon, and senior resident officer, in which capacities he proved himself an astute clinician and a tactful administrator, and became very popular with the students as a clinical teacher. In 1902 he was elected assistant surgeon, with charge of the aural clinic. His knowledge of otology soon became very thorough, and he did extremely good work in the production of a series of models of the labyrinth with fusible metal. He joined the Otological Society in 1903, and remained a member of the section after the amalgamation with the Royal Society of Medicine, and later he was made member of the council.

Considering his state of health, the amount of energy he displayed was wonderful, and he found time to act as secretary to the Bristol Medico-Chirurgical Society from 1903 to 1907, to the journal of which society he made several contributions. In 1909 he became full surgeon to the infirmary and clinical teacher in surgery to the university, and continued as such until 1916, when ill health compelled him to relinquish these posts.

None who came in contact with him could fail to be attracted by his personality. Punctual in habit and precise in action, he combined a cultured mind and a keen sense of humour with a rare appreciation of his responsibilities, which rendered him a charming companion and an exceptionally valuable member of the profession.

It was a bitter disappointment to him that in 1914, owing to illness, he had to resign his commission in the R.A.M.C.(T.F.), after serving for two months. He married in 1913, and leaves a widow and two sons.

A. L. F.

DR. GEORGE KILPATRICK GIVEN died at his residence at Muswell Rise on January 6th, aged 71. He received his medical education at the Ledwich School, Dublin, and Queen's College, Belfast, and took the diplomas of L.R.C.P. and S.Edin. in 1869 and the L.M.Dub. He practised for many years at Gortin, co. Tyrone, where he was physician to the Infirmary and Fever Hospital, M.O.H. to the Gortin Dispensary District, and consulting M.O.H. to the Gortin Union. He was also a magistrate for county Tyrone. He had been in failing health since the loss in March, 1915, of his youngest son, who was on board the ss. *Falabar* when she was torpedoed. He leaves a widow, one son, who holds an appointment as staff surgeon in the Royal Navy, and one daughter.

DR. HERBERT WHITLEY SKEY WILLIAMS, of P. Is-yndre, Holywell, died in London on December 15th last, to the deep regret of a large circle of friends and patients. Born on June 29th, 1869, the elder son of the late Dr. James Williams of Holywell, he was educated privately. He studied medicine at University College Hospital, London, and took the diplomas of M.R.C.S. and L.R.C.P. in 1892. He was at different times ambulance surgeon at the Northern Hospital and house-surgeon at the Royal Infirmary, Liverpool, and later joined his father at Holywell, gradually succeeding to the entire practice. In September last, owing to the breakdown in his health, he was compelled to leave home. He was medical officer of health for the Holywell Urban District, district medical officer under the Holywell Rural District Council, public vaccinator, one of the medical officers of the Flintshire Dispensary and Cottage Hospital, certifying factory surgeon for Holywell District, and held other public professional appointments. He was Justice of the Peace for Flintshire and was also a member of the military tribunal for the Holywell area. More than one of the above appointments had been held by his father and grandfather before him, the records of the family practice being traceable back for one hundred years. Dr. Herbert Williams was also in former days an enthusiastic member of the local volunteer company attached to the Royal Welsh Fusiliers, while during the war he was largely instrumental, as captain, in forming and maintaining the present local company of volunteers. He was greatly liked and esteemed throughout the district and by many friends elsewhere. He married in 1910 the daughter of General Inglis of Ryde, who, with two little children, survives him.

DR. JAMES COLLINGS HOYLE died on January 8th at Upham, Hants, aged 50. After studying medicine at St. Bartholomew's Hospital he took the diplomas of M.R.C.S., L.R.C.P. in 1889, and graduated M.B., B.S. of the University of Durham in 1894 and M.D. in 1913. He obtained the D.P.H. in 1892 and held for some years the post of M.O.H. for Gray's Inn. In 1896 he was appointed health medical officer for Rangoon and secretary to the Plague Council for Burma, but after four years was compelled by ill health to resign these posts, to the great regret of all who knew him. During the next year or two he made voyages in search of health, and then settled in practice at Upham in 1892. He was appointed assistant county medical officer of health to the Hampshire County Council in 1911, and later was given charge of two tuberculosis dispensaries. Unfortunately his health again broke down in 1915. For a year or so he acted as medical officer to the Royal National Sanatorium, Bournemouth, but last year he had to give up work entirely. Dr. Hoyle was a man of much zeal and ability, with a very marked capacity for inspiring affection and confidence in all with whom he came in touch.

Medical News.

THE appointment of Frank Cole Madden, M.D., Melb., F.R.C.S. Eng., Professor of Surgery, Egyptian Government School of Medicine, and Senior Surgeon to Kasr-el-Ainy Hospital, Cairo, as Honorary Medical Adviser to His Excellency Sir Reginald Wingate, G.C.B., High Commissioner for Egypt, has been approved by His Majesty's Principal Secretary of State for Foreign Affairs.

THE Research Defence Society and the Association for the Advancement of Medicine by Research have been united into one society, which will retain the name and official address of the Research Defence Society. All such communications as used to be made to the Association for the Advancement of Medicine by Research should now be made to the Research Defence Society, at 21, Ladbroke Square, W. 11.

THE first of a course of nine public lectures, on animal life and human progress, at King's College, London, will be given by Professor Dendy on Wednesday next, at 5.30 p.m. The lectures will be continued weekly on Wednesdays at the same hour. The lecture on March 6th, when Sir Patrick Manson will be in the chair, will be given by Dr. R. T. Leiper, Reader in Helminthology at the University of London, on "Some inhabitants of man and their migrations."

MR. EDMUND GOSSE, chairman of the London Library, informs us that that institution has arranged to act as a collecting centre for books, to assist the Red Cross and Order of St. John. Those members of the public who do not use the Post Office scheme are invited to send literature to the Librarian, London Library, St. James's Square, London, S.W., where it will be sorted. Any valuable books will be sold to buy larger numbers, and the whole given to the Red Cross War Library for distribution to the sick and wounded men of the navy and army.

AT the January meeting of the Illuminating Engineering Society Mr. L. Gaster read a paper, in which he discussed the future prospects of illuminating engineering. One of the immediate tasks of the society should be, he said, to obtain statistics showing the prejudicial effects of inadequate and unscientific lighting on the health and eyesight of factory workers. The Health of Munition Workers Committee had produced some evidence that inadequate lighting was prejudicial to health, and might cause headaches and other effects of eyestrain, apart from the fact that it also led to industrial accidents. The society intends to make a detailed survey, in order to place the matter beyond all question.

A CORRESPONDENT who has recently been called up for a fourth medical examination writes to the *Cambridge Daily News* in praise of the new arrangements made by the Ministry of National Service. On the day that he attended the Cambridge office not more than twenty others were called up for examination. The rooms were well warmed and everything possible was done for the comfort of the men. The examination by the four doctors forming the medical board was thorough and individual, and the men were treated with every consideration. After passing through the hands of each member of the board the men were informed by the chairman of the grade in which they placed, and within a very few minutes their cards were handed to them, together with an order for a day's pay to be paid next door. The writer concludes that if everything is done elsewhere as it is done at Cambridge there will be little cause for complaint.

AT a meeting of the Medical Society of Magdeburg, Dr. A. Weinert reported several striking cases of sudden death among soldiers who only a few minutes or hours earlier had been on duty. In several cases of diphtheria in which the diphtherial membrane was spread over the pharynx, larynx, and the whole respiratory tract the patient had remained on duty till about two hours before death. One patient suffering from abscess of the larynx had been off duty only half an hour when he died. One rare cause of sudden death was due to haemorrhage into the suprarenals after a fall. In three cases there were fatal haemorrhages from gastric ulcers, while the patients were also suffering from pneumonia. In a recent paper by Beitzke eleven cases of sudden death among soldiers are recorded in which, at the necropsy, nothing serious enough to be fatal could be found apart from early nephritis; but this was slight.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ARTISTS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Athology*, Westrand, London; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

PAINLESS CHILDBIRTH.

DR. G. BLACKER 45, Wimpole Street, W.) writes: In view of the interest which the subject of "twilight sleep" is exciting at the present time I am anxious to obtain authentic details of any cases in which this method of narcosis has produced dangerous symptoms or a fatal result in either the mother or the child. If any of your readers can furnish me with the particulars of any such cases I shall be greatly obliged.

PAY OF ANAESTHETISTS IN MILITARY HOSPITALS.

ANAESTHETIST in military hospital wishes to know if any other medical officer holding a similar appointment has applied for the special pay of 2s. 6d. a day, and if so whether his application has been successful.

INCOME TAX.

"X" who before the war was in partnership, is now serving abroad and has let his house; he holds certain War Loan stock. The point is whether he is resident in this country.

The residential test would seem to be the same with regard to the exemption from tax on war loan as in the ordinary case of relief from earned income. The special provision contained in Sec. 71 (1) of the Finance (1909-10) Act 1910 provides that a person employed in the service of the Crown abroad shall be entitled to relief "as if he were resident in the United Kingdom," though in computing the total income for the purpose of determining the rate of relief the non-chargeable income would have to be included. We suggest, therefore, that on the facts stated "X" would have reasonable grounds for claiming (1) that his war loan interest is at present exempt from duty and (2) that he is entitled to relief in respect of the rate of tax chargeable on his partnership profits on the special ground that he is employed in the service of the Crown abroad.

ANSWERS.

FINGER CRACKS.

DR. C. J. B. JOHNSON (King's Heath) sends the following suggestion: Heat a piece of shoemaker's wax and fill the crack with it. One application is generally sufficient. The objection to it is the dirty appearance. As a preventive the hands should be thoroughly rubbed with vaseline or oil before washing.

"X" writes: I have had the best results from a solution of celluloid (old photographic film, well cleaned). Dissolve in ether and thin down with amyl acetate. The crack must be perfectly dry, and be kept on the stretch (gaping) till repeated coats of the solution have dried in and filled it up. The essential point to remember is that the object is not to bridge over the crack, and still less to draw its sides together, but to fill it up solidly from the bottom. If well done, it should last, in spite of free use of the finger, washing, etc., till the skin outgrows the crack. Only in extreme cases need a few fibres of cotton-wool be added. This solution adheres better than collodion.

ICHTHYOSIS writes: In my personal experience of this disability, which is considerable, the only treatment I have found really useful is that recommended to me a number of years ago by the late Dr. Allan Jamieson of Edinburgh. A thin wisp of cotton-wool is fixed over the crack (with a good grip of the adjacent nail) by means of "epicollod," a collodion preparation made by Messrs. Duncan and

Flockhart of Edinburgh, and more adhesive and durable than any of the other similar preparations I have tried. It is neater and cleaner than plaster, can be washed and scrubbed repeatedly, and will often remain in place for two days or even longer. The cracks heal up rapidly beneath it and commencing ones can usually be aborted by its use.

LETTERS, NOTES, ETC.

MIRROR WRITING AND WRITING WITH THE LEFT HAND.

DR. WILLIAM ELDER (Leith) writes: In amplification of the letter and notes in the BRITISH MEDICAL JOURNAL of January 19th I wish to point out to those interested that they will find the subject of mirror writing discussed in my work on *Aphasia and the Cerebral Speech Mechanism* in 1897 and the article on mirror writing in *The Encyclopaedia Medica*, vol. viii, 1901. In these articles I offered what I believe to be the explanation of what Dr. Heywood Smith and you state as a curious fact that mirror writing can be at once identified as the person's handwriting as it reproduces the characteristics of the particular individual's right handwriting. It would require too much space to summarize the explanation here, but I believe that the movements that produce mirror writing are guided from the left cortex just as the movements of the right hand are guided in ordinary writing. Mirror writing results from bilateral representation of the movements of the hands, etc.

Every one, however, is not a true mirror writer, even although he may be able to write backwards with the left hand, as the statistics of experiments I published in those articles showed. Probably a greater number can be found amongst quick expert writers and individuals of special aptitude. It has also to be noted that the calling into action of the eyesight rather interferes with the production of mirror writing.

The suggestion of Sir James Barr is an excellent one, namely, to write with the left hand on paper backed with carbon paper so that the mirror writing can be read on the reverse side. For those poor fellows who have lost their right hand this is a means by which at once many of them could write letters with their left hand without going through the rather painful and patient process of learning to form the letters in the ordinary way, but it is to be remembered that probably practice of mirror writing with the left hand will rather retard the progress of the pupil who is learning to write in the usual way with the left hand.

COLD-CATCHING DANGERS.

DR. T. REUELL ATKINSON (Chadwell Heath) writes: A few days ago an article with the above heading, by a "Medical Correspondent," appeared in a daily newspaper. He stated that "bronchitis and pneumonia were among the most fatal of cold-catching diseases"—a slightly involved statement, but is it true? Do either of those diseases owe their origin to cold? One often reads that So-and-so caught a chill and pneumonia followed. But was not the chill the evidence of the onset of the pneumonia? For many years I have held the view that the simple bronchitis and bronchial catarrh so prevalent in our climate in winter were due to the usual shutting up of doors and windows and sitting in a stuffy and often smoke-laden room, theatre, cinema, church, or chapel—"gassed," in fact, in a mild form. Is not the cough of so-called bronchitis and bronchial catarrh more often laryngeal or pharyngeal? Acute bronchitis as a disease *per se* I seldom or never see. Does any one? In the JOURNAL for February 15th, 1913, I described the good results I had obtained in these winter cough cases by the use of an inhaler, made by Squire, on which a few drops of a solution of iodine, creosote, carbolic acid, and chloroform were placed, worn and kept on all night. One night's inhalation often cures. After repeated trials, I have as strong a faith now as then in its efficacy. The laity have a horror of cold and chills and draughts, which is kept alive by "medical opinions" so often given in newspapers. Hence stuffiness is rampant in people's homes, and, worst of all, in the little cottage rooms of the poor.

SKIN GRAFTING.

TEMPORARY CAPTAIN R.A.M.C. writes: None of the points of interest mentioned by Dr. H. C. Crew (January 19th, p. 84) are novel. In my student days at Guy's in the nineties I remember skin grafts of foreskins being used. They were washed in warm boracic lotion, and kept in the lotion until required for use. As far as I can recollect it was often considerably longer than two hours from the time of the circumcision to the "planting" of the grafts. Success was not invariably with the grafts, but the majority "took."

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

J. K. P., in the course of a letter continuing the discussion on this subject, expresses a strong opinion that the present ruling of the Army Council as to medical students who are at present in the army is grossly unfair to those students who do not come within the purview of the order. The present situation cannot, however, he thinks, be laid at the door of the War Office authorities, who only look at the military aspect, and care nothing about what the loss of study may entail to the student or his parents. The question first came up at the annual meeting of the British Medical Association in July, when a resolution was brought forward that all bona fide medical students should be released from military service

and allowed to resume their studies. This resolution got short shrift. A member immediately proposed that the meeting should pass to the next business, and this was carried without a word of protest. Since then, although the subject has come up in various forms, neither the General Medical Council nor the British Medical Association, through the Central Medical War Committee, has shown much interest.

So long as the colleges and universities can retain sufficient students to "carry on," the future welfare of the medical student who is in the army does not seem to be any concern of theirs. The function of the Central Medical War Committee is to keep the army supplied with medical officers. So long as that duty is carried out to the satisfaction of the military authorities during the present emergency the future of the medical student or the profession after the war will not worry them very much.

Why should the medical student be put in a different category to the apprentice fitter? The former is necessary to keep up the supply of medical officers for the army, the latter the supply of skilled artisans for munition works; one class gets total exemption, the other, to put it at its best, a "make believe." The reason is, of course, that the trade union of the artisan sees that he is not interfered with, whilst the medical student has only the General Medical Council and the British Medical Association to protect his interests. The patriotism of the boys who left their studies before being compelled to do so has received treatment of which neither the profession nor those who are supposed to look after its interests can feel proud. The equitable and just solution is quite simple. Why should not all medical students be required to serve for one year, at the termination of which they should be compelled to resume their studies? Those joining up would balance those coming out, and a year's loss of study could be easily overtaken.

J. A. A., in the course of a letter on this subject, writes: It may be of interest to relate the story of three medical students, A., B., and C., who commenced their medical studies together in 1913. They passed their first professional examination in June, 1914, before the war broke out, and commenced their second year together in September, 1914.

Then came the great appeal to the patriotic instincts of young men. A. left his studies and enlisted at once. Within six months he was fighting in Gallipoli, later in Mesopotamia, and is still, after three years, risking his life daily in the service of his country.

B., held back maybe by the appeals of those whose wishes he was bound to respect, resisted the daily taunts of his professors until he had passed his second professional. Then, when conscription was looming large, he joined, but within a few months was able to take advantage of the A.C.I. of December, 1916, and return to his studies. He is now well on his way to becoming qualified.

C., neither heeded his country's call nor his professors' sneers, and risked the coming of conscription. His super-patriotism was rewarded by total exemption, and whilst A. was bleeding for his country on the plains of Mesopotamia, C. was gathering in the spoils of a unique experience as unqualified (salaried) house-surgeon in a large hospital attached to his university. He was enabled by special concessions to enter for his final examination six months earlier than usual, but remembering, at the last moment, that should he qualify he would be required to show his patriotism where shells were bursting, he decided to postpone his final as long as possible, until, I suppose, the end of the war approaches. It appears that a man need only become a fourth year student and he is safe for the duration of the war, provided he is wise enough not to qualify. He simply acts as unqualified house-surgeon, obtains all his experience (and salary), and runs no risk. But if a man comes home under A.C.I. 1751, he must, no matter how long he has been away from his books, pass his examination within six months or be recalled ignominiously to the ranks.

You, Sir, on page 90 of last week's issue, appear to make some sort of apology for this state of things. I am a loyal member of the British Medical Association, but I venture to think that if the officials of the British Medical Association had sons suffering under this outrageous injustice, such cold comments on such a burning question would not appear in the JOURNAL. Surely it is not beyond the wit of man to combine fair treatment to the patriots of 1914 with national expediency. Let those responsible (including the British Medical Association) see to it.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postie restante* letters addressed either in initials or numbers.

Remarks

ON

THE ETIOLOGY OF DIABETES MELLITUS

AND THE DIET AND CONDITIONS OF LIFE
DURING THE WAR.By R. T. WILLIAMSON, M.D.LOND., F.R.C.P.,
CONSULTING PHYSICIAN, ROYAL INFIRMARY, MANCHESTER.

WHATEVER may be the exact pathology of diabetes mellitus, certain etiological relations are of much interest and of some importance with respect to the prevention of the disease in England during this period of overstrain through the war.

Diabetes mellitus has been steadily becoming more frequent for many years. The death-rate from the disease has increased in England and Wales from 59 per million living in 1886, to 97 in 1906, and to 130 in 1915. The larger portion of the increased mortality rate may be clearly attributed to the increased frequency of the disease.

In 1908 I collected all the information I could obtain respecting the frequency of diabetes in various countries, and obtained information from all quarters of the world. Some was reliable, some unsatisfactory.¹ My conclusions were:

The mortality from diabetes is much greater than in England and London, in the following towns and countries: In Malta, in many of the large towns of the United States (Worcester, Syracuse, Rochester, New York, Boston, Washington), in Bordeaux (France), in Berlin, Paris, Frankfurt (am Main). Also experience indicates that diabetes is especially common in Bengal, Ceylon, Siam, and Tunis. Certain races are especially liable to suffer: Jews, Hindus, and Maltese. In 1907, the year when my statistics were collected, the mortality for diabetes per 100,000 living in Malta and Gozo was four times that in England and Wales. In New York, Washington, and Boston (United States), and in Paris it was twice that in London. In Worcester (United States) and Syracuse (United States) and in Bordeaux (France) it was three times that in London.

Is more sugar and sweet food taken in these countries and by these races than in England? In many of the towns of the United States, and in Malta and Tunis, I understand that this is the case. May this be a predisposing cause and account for a portion of the greater frequency of the disease in these countries and races?

If we take the history of a large series of cases of diabetes we find the disease has very frequently followed certain conditions. We cannot say that these conditions were the cause of the disease, but the history of such conditions before the disease has been detected has been so frequent that they cannot be regarded as coincidents. Whatever other cause or causes there may be, they may very fairly be considered as at least extremely probable predisposing causes. If the patients had not been exposed to these conditions they would not have suffered from the disease until a much later period, or possibly not at all. In other words, the onset of the disease has been at least accelerated by these conditions of life or habits.

The etiology of diabetes is discussed in detail in textbooks and monographs, and in this article I desire to draw attention to three predisposing causes only. In 1898² I published an analysis of the etiology in one hundred consecutive cases. Since that time I have taken notes on the etiology in most cases I have seen, and my results respecting the frequency of certain predisposing causes have been much the same. More recently I have inquired very carefully in another series, of 300 cases, respecting the frequency of (1) great and prolonged excess of sweet food and drinks, chocolate, etc.; (2) very great and prolonged mental anxiety, worry, and overstrain, or sudden shock; (3) family history of the disease. Other points in the etiology were also noted. I have asked questions on ten points, and collected the answers on separate slips of paper. (Most of these cases were seen before the war.) Though the answers varied much, the most striking points in the history in these cases were (1) the frequency of great excess of sweet food or drink for a long period before the onset of the disease; (2) the frequency of prolonged mental anxiety, worry, or sudden shock just before the onset of the disease; (3) the frequency of a family history

of diabetes. This is shown by the following results respecting the etiology in 300 cases:

History of prolonged great excess of sugar, sweet food, or sweet drinks (alone or combined with other predisposing causes) in 93 (= 31 per cent.).

History of prolonged and intense mental anxiety, worry, overstrain, or sudden mental shock (alone or combined with other predisposing causes), in 120 (= 40 per cent.).

Family history of diabetes (alone or combined) in 76 (= 25 per cent.).

No definite predisposing cause in 59 (= 19 per cent.).

The following are the results in detail, especially with respect to these three questions.

I. *Very Great Excess of Sugar, Sweet Food, and Sweet Drinks.*

A previous history of prolonged great excess of sugar, sweet food, chocolate or sweet drinks, alone or combined with other predisposing causes, was obtained in 93 out of 300 cases (31 per cent.). If we consider these cases in detail we have the following groups:

(a) Great excess of sugar, sweet food, chocolate, or sweet drinks ...	40 cases.
(b) Ditto, plus great mental worry, anxiety, strain, or sudden mental shock ...	19 "
(c) Ditto, plus great overstrain in work ...	4 "
(d) Ditto, plus mental overstrain, anxiety, etc., and great overstrain in work ...	6 "
(e) Ditto, plus family history of diabetes ...	13 "
(f) Ditto, plus family history, plus mental or physical overstrain or shock ...	9 "
(g) Ditto, plus severe injury ...	2 "
93 cases.	

The history showed that these patients had taken very large quantities of sugar in tea and foods, or very large quantities of jam, or sweets, or chocolate, or very sweet fruits and other very sweet foods. In many cases the patient had taken tea in very large quantities, containing much sugar, three times a day.

Chocolate had been taken in very large quantities by 21 of the 93 patients, either alone or with other sweet food or drinks. In some of these cases a history was also obtained of mental overstrain or shock, physical overstrain or a family history of diabetes.

Apart from the excess of very sweet tea already mentioned, in 17 of the 93 cases great excess of other sweet drinks had been taken for a long period before the onset of diabetes—herb beer containing much sugar or treacle, ginger beer, whisky with much sugar, sweet wines, gin and ginger beer, cider, sugar and milk. In some of these cases often other sweet food had been taken freely, or a history of mental overstrain, shock, or physical overstrain, or a family history of diabetes was obtained. Great excess of jam (jam at nearly every meal), great excess of chocolate, great excess of tea containing much sugar (in one case thirty-six lumps of sugar in the tea daily), and great excess of herb beer containing much sugar or treacle (in one case 8 pints daily), were striking points in the histories of certain cases.

The following are a few examples of the continued excess of sugar and sweet foods or drinks taken for long periods before the onset of diabetic symptoms:

1. Female; stated that she had "lived on sweet food": great excess taken; jam taken freely "at nearly every meal." Excess of sweet drinks, including herb beer containing sugar.

2. Female; stated that she had "lived on sweet food": had taken sweet food at every meal; sweet fruit, jam, sweet cake, and chocolate, all taken in excess. Sweet lemonade taken freely.

3. Male; great excess of sweet food; half a pound of jam daily (½ lb. for breakfast and ½ lb. for tea); tea three times a day, with 18 teaspoonfuls of sugar (about 4½ oz. of sugar daily); beer four or five glasses daily; whisky twice a day; wine occasionally. Overwork; great mental strain and worry.

4. Male; excess of sweet food; half a pound of jam daily (½ lb. for breakfast, ½ lb. for tea); sweet food at dinner; 4 to 6 oz. of cream chocolate daily; sweet tea three times a day (containing nearly 2 oz. of sugar); herb beer and sweet lemonade freely.

5. Male; great excess of sweet food and sugar; 3 lb. of chocolate weekly; 20 lumps of sugar (nearly 4 oz.) in tea daily. Great mental strain and overwork.

6. Female; excess of sweet food; about 25 lumps or more of sugar (about 4 to 5½ oz. of sugar) in tea daily; herb beer 1 pint daily; bitter beer also taken daily.

7. Female; 36 lumps of sugar in tea alone daily (about 6½ oz. of sugar). Great mental worry.

8. Male; great excess of sweet food and sugar (about 4 oz. of sugar in a pint of tea); about 6 oz. of sugar daily; 4 oz. of "sweets" daily; half a pound of sweet cake daily; beer taken freely.

9. Male; excess of sweet food; 4 oz. of chocolate daily; tea three or four times a day, well sweetened ($\frac{3}{4}$ to 4 oz. of sugar in tea alone daily). Great mental overstrain.

10. Male; 19 teaspoonfuls of sugar (about 4 oz.) daily in addition to other sweet food.

11. Male; medical man with heavy practice in Scotland. Breakfast early, dinner very late in evening; "lived on chocolate" between these hours; no midday meals very frequently except chocolate. Great excess of chocolate daily.

12. Male; sweet food in excess; half a pound of sugar daily: great mental strain and worry.

13. Male; great excess of sweet food; tea very sweet; herb beer containing much sugar (8 pints) daily in summer (4 in winter). Great mental strain and hard work.

14. Male; great excess of a mixture of gin and ginger beer daily.

15. Male; three pints of herb beer daily; port wine rather freely. Great mental strain in work.

16. Male; five bottles of herb beer (containing much sugar) daily. History of a fall followed by neurasthenic symptoms.

17. Male; ten glasses of whisky daily well sweetened with sugar.

18. Female; great excess of whisky very well sweetened with sugar.

In a number of cases in young children a history was obtained of great excess of sweet food, with a large quantity of chocolate daily or a large quantity of sweets.

19. Baby 14 months old; had been fed on milk to which the mother added large quantities of sugar. Severe diabetes; death in two weeks.

II. Prolonged and Intense Mental Anxiety, Worry, Overstrain, and Sudden Shock.

Willis (the English physician who first discovered that the urine in diabetes had a sweet taste) 240 years ago attributed the disease to sadness and long sorrow, and from that date numerous writers have pointed out that the disease sometimes follows prolonged and intense mental anxiety, overstrain, worry, or severe mental shock. Such a history I have obtained in a large percentage of the cases of which I have notes during the last thirty years.

The following are the statistics in the series of 300 cases on which this article is based.

The disease followed directly after a period of intense and prolonged mental overstrain, anxiety, or worry, or after a sudden very severe shock in 120 out of 300 cases (= 40 per cent.).

In these 120 cases we had a history of mental overstrain, anxiety, or shock alone in 61; along with a family history of diabetes in 25; along with a history of great excess of sugar or sweet food or drinks in 25; along with a history of excess of sugar and a family history of the disease in 9.

Often associated with the mental overstrain, anxiety, or shock we have a history of physical overwork and overstrain and long hours of work, or occasionally a history of acute illness or alcoholic excess or other predisposing causes.

A history of sudden mental shock immediately before the onset of the disease is occasionally obtained (13 out of the 120 cases). Often the disease directly followed the mental overstrain and anxiety caused by the death of a relative, or by the prolonged illness of a relative, or by nursing a relative through a long or critical or fatal illness (12 out of the 120 cases). Very often we had in these cases a history of great loss of sleep and of physical overstrain.

Often we had a history of great anxiety and mental overstrain through losses in business, frequently associated with overwork, and frequently with loss of sleep, and occasionally with excess of alcohol. Occasionally a history was obtained of excessive mental work in preparing for examinations and prolonged hours of close study just before the onset of the disease (5 of the 120 cases).

The loss of sleep, so often associated with sorrow and anxiety caused by the death or illness of a relative, by sudden mental shock, or business losses, in the cases just mentioned, is probably a very important point.

The two following cases are of interest with respect to sudden mental shock:

20. A lady who had just been confined developed diabetes directly after a sudden mental shock. The nurse was warning the baby before the fire. The nurse dozed, or fell asleep, for a short time, and held the baby too close to the fire, and the

baby's legs were severely scorched. This caused the greatest shock to the mother; she was never well afterwards. In a few days symptoms of diabetes were noted. Previous to the shock the lady had been quite well, and the urine had been tested towards the end of pregnancy and found free from sugar.

21. In a man aged 57 symptoms of diabetes followed rapidly after a sudden mental shock. Four months previous to the shock he had passed a medical examination for life assurance, at which his urine had been tested. Whilst playing cards, the friend with whom he was playing died quite suddenly at the table. This caused the patient the greatest shock; he was never well afterwards. Within one week of the shock thirst and symptoms of diabetes were first noted.

III. Family History.

A family history of diabetes was obtained in 76 of the 300 cases = 25 per cent. Many striking instances were noted.

A history of great excess of alcohol was obtained in only a small proportion of the cases, much less frequently than a history of excess of sugar, or of mental anxiety or shock, or a family history of diabetes. In the statistics published in 1898 (chiefly hospital patients) I found a history of great alcoholic excess in 17 per cent. Amongst the private diabetic patients such a history was much less frequently obtained.

It is interesting to note that glycosuria occurs in some cases of Graves's disease. Occasionally the symptoms of Graves's disease diminish markedly, or cease, and symptoms of severe diabetes develop.

In many cases of acromegaly glycosuria or well-marked diabetes develops.

Diabetes sometimes follows directly after an acute illness, and the history often shows many other interesting etiological relations, but it is only to the three predisposing causes just considered that I desire to draw attention in this article.

In some cases no predisposing or exciting cause can be found (in 59 of my last series of 300 cases).

In statistics of a previous series of cases (1908) I obtained a history of great mental anxiety, shock, and overstrain in 35 per cent.; history of very great excess of sugar, sweet food or sweet drinks in 37 per cent.

This consideration of the etiology of diabetes shows the frequency, and I think the importance, of three predisposing causes: (1) Prolonged mental worry, anxiety, great mental strain, or sudden great mental shock, sometimes associated with overwork; (2) excess of sugar in the diet—sweet food or drinks, and excess of chocolate; (3) family history of the disease. Often we find a history in the same case of a combination of two or all three of these.

From my own experience in Manchester I think we shall find that diabetes has increased in frequency amongst the civil population of England since the war commenced. Amongst those who are doing military service I think we shall find that diabetes has not been much more frequent than amongst men of the same age in civil life before the war, but this is an impression, and not based on definite statistics. If correct, possibly the increased exercise and better regulated diet, in which great excess of sugar and sweet food is not allowed, may account for diabetes not being more frequent amongst those engaged in military work. Possibly also they have less time for brooding and worrying than people in civil life. We may find, however, that many who are now suffering from shell shock, neurasthenia, and functional nervous diseases will develop diabetes later.

Prevention of the Disease.

We cannot alter our family history, but we can all avoid excess of sweet food, sweet drinks, sugar, chocolate, and sweet jam during the war; and though we cannot avoid mental worry, anxiety, and shocks, we can often do something to diminish their effects.

It is important for all to avoid excess of sweet food, jam, chocolate, sugar, and drinks containing much sugar; but more so for those who have great mental strain, anxiety, and overwork, and especially for those who, in addition, have a family history of diabetes. The sugar restrictions will do much to check the excess of sugar in tea and coffee and in cooking, but we have as yet no restriction directly as to jam, chocolate, and many articles of sweet food. Those who have great mental anxiety and overstrain, and especially if they have also a family history of diabetes, would do well to discontinue the addition of sugar in tea, coffee, and in food entirely, and to limit to the minimum the use of

jam, sweet foods, chocolate, and drinks containing much sugar, such as herb beer, sweet wines, and combinations of sugar and alcohol. They would thereby be helping the Food Controller, as well as doing something to diminish their own risk of diabetes.

Alcohol, and especially combinations of alcohol and sugar, if they can still be obtained, should be very limited in the case of those who have much mental strain, anxiety, or worry. The regulations now in force will check any excess for most people.

Through the war, we are now all suffering, more or less, from mental overstrain, worry, anxiety, or sudden mental shocks, which will tend to increase the risk of diabetes. We cannot avoid them, but we can do something (and this is especially desirable in those who are suffering severely) to diminish their effects by directing our attention, whenever possible, to subjects not directly associated with the particular anxiety or worry, and especially by close occupation. Most people have now to work very hard, and occupation and close attention to work are useful in diminishing the effect of mental shock and anxiety; but when the overwork is excessive something may be done to diminish the injurious effects by putting aside any work not absolutely necessary, if this is possible.

Sleep is very important. When insomnia is associated with the great mental strains already named prompt treatment is desirable, and, if it cannot be checked, drugs such as chloralamide, trional, adalin, etc., taken under the direction of a physician for a short time, may be of much service.

Summary.

It is desirable for all to cut down sweet foods and drinks, chocolate, jam, sugar, and alcohol to a minimum during the war, and especially for those who have a family history of diabetes, and are suffering from great mental strain or shock; they will thereby help the Food Controller and also diminish the risk of diabetes. Occupation and close attention to work are useful in diminishing the effects of mental worry and shock, and thereby the risk of diabetes, but in certain cases of excessive overwork it is desirable to cut off work not absolutely necessary, if this is possible; sleep is very important.

The recent food restrictions, as already mentioned, will check for most people any excess of sugar and alcohol, and will thus tend to diminish the risk of diabetes. Those who have been obliged through these restrictions to discontinue excess of alcohol or sugar should, however, not replace these by excess of non-alcoholic drinks containing much sugar, and excess of jam, chocolate, and other sweet foods which may be still obtainable.

THE EFFECT OF INTERMITTENT STRETCHING ON MUSCLES AND NERVES AFTER NERVE SEVERANCE.

By J. N. LANGLEY, Sc.D., LL.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY, CAMBRIDGE.

ONE of the problems of the treatment of cases of nerve severance is the time during which movement of the paralysed muscles can be allowed and the extent to which it can be carried on with safety. In the period before suture the practice is to allow some degree of movement, and Sir Berkeley Moynihan,¹ in a recent paper, says that in order to keep the joints supple the paralysed parts must be freely moved every day, and many times a day. On the other hand, for a certain time after suture, no movement at all is allowed. The necessity of this has been specially insisted on by Sir Robert Jones,² who has had a wide experience of nerve suture cases.

The statement that movement is not permissible for some time after nerve suture is usually given in the form that the muscle during this time must be kept completely relaxed, or that the muscle must not be stretched. Thus Sir Robert Jones² says that "the slightest stretching of a muscle on the point of recovery disables it again," and Sir Berkeley Moynihan¹ that "not for a moment at any time must paralysed muscle be stretched." These are no doubt merely practical directions to avoid delay in recovery,

but the natural inference from them is that any degree of stretching is injurious to the muscle, and that it is this injury which delays the recovery. The inference is strengthened when it is at the same time pointed out that prolonged stretching of a muscle causes permanent elongation. So far as this inference is made it must tend to restrict movement before nerve suture, for if stretching is injurious to a muscle after suture it will be injurious to it for more or less time before suture. In any case it is necessary for satisfactory treatment to know what degree of stretching not only paralysed muscle but also degenerating and regenerating nerves will stand. I venture, then, to offer some remarks on these points, although my experiments are incomplete. Unless otherwise mentioned, I only consider the stretching produced by intermittent ordinary joint movement, and not the protracted stretching caused by the unrestricted action of antagonistic muscles. We may consider separately the effect on muscles and the effect on nerves.

I. STRETCHING OF MUSCLES.

The effect of intermittent stretching on muscles might *a priori* be either advantageous or the reverse, according to the weight which is laid on particular events. On the one hand, it forces lymph from the muscles, and so presumably metabolic products, and this we should expect to be advantageous. Further, it seems not unlikely that it is of advantage in relation to connective tissue formation. In denervated muscles the connective tissue increases—it is said to be visibly increased in microscopic preparations three weeks after nerve section—and part of the late contracture is attributed to the shrinking of the newly formed tissue. The connective tissue when first formed is soft and extensible. Intermittent extension will elongate the developing fibres, so that when they shrink there may be less tendency to contracture. On the other hand, muscles after denervation rapidly lose weight—in cats and rabbits the gastrocnemius loses about 50 per cent. of its weight in about four weeks—and it is practically certain that in this state it cannot stand as great a strain as normal. Whilst a great reduction in its power of withstanding strain might take place without making it liable to be injured by the degree of strain put on it by free joint movement, we cannot offhand say that free movement does not injure it. Observations on man can hardly settle the point, since the effect has to be judged by the rapidity of regeneration, and this is greatly influenced by the events after nerve suture. In animals a more definite result can be obtained by noting the effect of intermittent tension on the appearance of the muscles and on the degree of atrophy.

A short time ago I published an experiment³ on these points. The popliteal nerves in a rabbit were cut on both sides, and the leg and foot on one side rhythmically extended and flexed for an hour morning and evening.

At the end of three weeks the animal was killed and the muscles of each leg weighed. The muscles had no obvious difference to the eye, and no sign of ruptured fibres. On the side on which the paralysed muscles had been rhythmically extended, four of the muscles were rather heavier than on the other side, one was of the same weight, two were somewhat lighter. The differences were not decidedly outside the normal difference of weight on the two sides in normal animals.

The experiment showed that stretching the paralysed muscle a great number of times to about the full normal extent did not in its total effect appreciably affect the atrophy. It must be noticed that, on account of the experimental error, a slight effect would not be appreciable unless a number of experiments of the kind given were made, and that irritability might be altered without an alteration in the loss of weight. Further, the total effect may have been the algebraical sum of + and – effects, but, from the practical point of view, this is unimportant. I have made incidental observations on muscles in later stages of atrophy up to about three months, and have seen no sign that they are injured by moderate intermittent tension, or by the degree of strain exercised by antagonistic muscles provided this is not prolonged.

II. STRETCHING OF NERVES.

Movements of joints and stretching of muscles exerts more or less pull on the nerves. The conditions affecting these are essentially different before and after nerve suture.

Stretching Nerves by Movement before Nerve Suture.

Nerve fibres pass through the two well-known stages of forming, first, a granular protoplasmic band, and then a hyaline band—the “band fibre.” The former lasts two or more weeks—its duration varying in different fibres—and its appearance suggests that it is very little extensible. Fibres in this stage sometimes show great inequalities in the granular band, which might be due either to tension or to inequalities in protoplasmic formation. It is unlikely that they are due to tension since the nerve in the early period after severance is free to move. In two to three weeks after nerve severance the cut peripheral end becomes more or less fixed to the surrounding connective tissue, and a given movement causes a somewhat greater pull on the nerve. I have tested the extent of this on the sciatic nerve and its branches in rabbits and cats. By complete extension or flexion of the limb the nerve may be straightened, but its tension so far as I have seen is too slight to cause injury, and I have not found that it causes any rupture of the degenerating fibres. It may, I think, be concluded that, in the pre-suture period, fairly free extension and flexion movements are not likely to injure either muscle or nerve. Naturally, forcible movements are always to be avoided.

In the pre-suture period there are some definite advantages in a flexible splint, allowing a certain amount of movement. Passive movement can be carried on at frequent intervals by the patient, and, when flexors or extensors are not paralysed, limited voluntary movements can be made, sufficient to prevent the wasting in the non-paralysed muscles which accompanies disuse.

Stretching Nerve by Movement after Nerve Suture.

We may consider first the simplest case—namely, that in which the nerve is not shortened. In this case movement will tend to strain the sutures and rupture the nerves growing from the central into the peripheral end. But connective tissue soon joins the ends, and binds them—at first loosely—to the surrounding tissue. Restricted movements can be made without injury, since these put extremely little tension on an unshortened nerve. When the connective tissue has become firm, tension on the nerves will not injure the nerves at the suture as readily as it injures the newly formed fibres and the “band fibres” in the peripheral part of the nerves, consequently whether full movement can be made or not depends on whether the tension caused by it is sufficient to injure the peripheral part of the nerve.

The following experiments, a further account of which has been given elsewhere,¹ bear on this question. In cats the peroneal nerve (Experiments 1, 2, 3) or the tibial nerve (Experiment 4) was compressed on one side sufficiently to break through the axis cylinders without breaking through the nerve sheath; the limb was left without a splint, so that the muscles would be extended by their antagonists for a greater or less time, according to the posture of the animal. The animals with cut peroneal nerve were allowed to walk about as they pleased; that with the cut tibial nerve was kept in a cage for a week and then allowed gradually increasing exercise. The recovery of nervous control was rapid. In Experiments 1 to 3 reflex abduction of the fifth toe was obtained after nineteen days; stimulation of the peroneal nerve caused fairly good contraction of all the extensor muscles of the leg in twenty-one days (Experiment 1), and strong contraction after thirty-six and thirty-eight days (Experiments 2 and 3). In Experiment 4, in which the tibial nerve was cut, the animal, after forty-eight days, could keep the heel well off the ground in walking; stimulation of the tibial nerve caused contraction of the flexors of the leg, and stimulation of the posterior tibial nerve—though with currents considerably stronger than normal—caused contraction of the muscles of the foot. On microscopic examination, all the nerve fibres were found to have undergone Wallerian degeneration.

These experiments show that in animals a considerable degree of movement does not prevent rapid regeneration in an unshortened nerve. The definitely ascertained facts with regard to the effects of nerve severance are so similar in man and animals that the results given above are, I think, applicable to man. I conclude that in cases of suture in man, when the nerve is not shortened, slight movements can be begun in a few weeks and rather rapidly increased in extent. Early movement probably has the advantage of elongating the connective tissue binding the nerve to the surrounding structures. The connective tissue in its later stages tends to fix the nerve and thus to cause the peripheral part of the nerve to be subjected to a greater strain during movement. In consequence, in cases

of nerve compression in which there has been considerable connective tissue formation, it is necessary in the later stages to be more cautious about movement than in cases of immediate nerve suture.

In the great majority of cases in man the nerve has to be shortened, and until the ends become firmly joined a very slight movement may be sufficient to rupture the fibres at the junction, and thus to cause a more or less serious delay in regeneration. Obviously the greater the shortening of the nerve the greater the risk. But even when the junction is firm there is still the risk of injuring the new fibres and “band fibres” in the peripheral part of the nerve, especially in the smaller branches, by even slight movement. There are unfortunately no comparative observations on the degree of strain degenerating and regenerating and normal nerve fibres will stand. If new fibres and “band fibres” throughout the peripheral end of the nerve can stand as much strain as the normal nerve, there seems no reason why movement should not be begun as soon as the union of the nerves is firm. If, on the other hand, new fibres and “band fibres” stand much less strain than normal nerves, it may be necessary to wait until the nerve fibres have become fully developed up to their terminations, and this in some cases would take many months. In any case, it is important to shorten the nerve as little as possible. It would, indeed, probably be better to insert a piece of fresh nerve, not more than half an inch, when much nerve has to be excised, but this can only be settled by experiment.

There is one other point I would mention. It is generally recognized that if a nerve has been severed the sooner it is sutured the better. The main reasons for this are that the longer a muscle is left to atrophy the longer time it takes in recovering its normal weight. At best it is a slow process. It is probable also that nerve regeneration is quicker if it is sutured before the central end has formed a large neuroma and before the “band fibres” have decreased in diameter. The practical difficulty is in distinguishing between complete nerve compression which will recover without operation and nerve severance which requires operation. Tinel² considers that this often takes two to three months. In simple compression new fibres are formed in the part of the nerve just below the point of injury long before there is any sign of recovery on stimulating muscles and motor points. If, then, this region could be stimulated without the stimulation spreading to the normal nerve it would give rise to sensation, and compression diagnosed. In certain cases it would, I think, be possible to do this by passing a needle covered, except at its point, with shellac through the tissues on to the nerve and stimulating with faradic shocks of gradually increasing intensity. If there were no sensory reaction a month after the injury a diagnosis of nerve severance would be much strengthened.

NOTE UPON A HELPFUL DIAGNOSTIC SIGN
IN RUPTURED DIGESTIVE ULCERS.

BY

R. J. WILLAN, M.V.O., M.S., F.R.C.S.,

STAFF SURGEON R.N.V.R.

HONORARY ASSISTANT SURGEON AND LECTURER IN CLINICAL SURGERY
TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

SEVERAL years ago I saw a patient, a hawker, upon his admission to the Royal Victoria Infirmary, Newcastle-on-Tyne, under Professor Rutherford Morrison. He was suffering from acute general abdominal pain of a few hours' duration, and so acute was it that he maintained a constant screaming such as incommoded the other patients in the ward. His doctor, a very careful practitioner, stated that the patient had many times consulted him for alleged sudden attacks of acute abdominal pain, which had just as suddenly passed off. Despite repeated careful examinations nothing abnormal had been discovered, and he came to be regarded as a probable malingerer.

Upon admission his overwhelming pain and a board-like rigidity of the anterior abdominal wall were evidence that

Some intra-abdominal viscera had ruptured. At operation a ruptured duodenal ulcer was found and dealt with. The feature about the case most deeply impressed upon my mind was the presence of a transverse ring of constriction across the abdomen at the level of the lower margins of the ribs, and extending into the flanks on either side.

I had not noticed this sign before, but since then it has often stood me in good stead in the diagnosis of ruptured digestive ulcers, particularly in an atypical case; my reason for recording it now is that it has just dawned upon me that as a helpful diagnostic sign this ring of constriction in perforated digestive ulcers is not generally known. Without claiming to have made an original observation, for at present I have no opportunity of investigating the literature of the subject, I have never previously either seen or heard this sign described. Some surgeons with experience of general hospital emergency work must be familiar with it. I cannot say definitely if it is limited to ruptured digestive ulcers, or if it is also seen in some other acute intra-abdominal lesions. My impression is that I have also seen it in one other instance, namely, a traumatic rupture of the jejunum high up, but I am not positive about this without reference to notes which are not at present accessible.

The constriction is usually present, and does not always disappear with general anaesthesia, although it does disappear when the condition has advanced to the stage of general abdominal distension. There is no marked hyperaesthesia, and the patient is quite unconscious of any feeling of tightness at the site of the constriction. It is not confined to spare or emaciated persons, and is a different thing altogether from the scaphoid abdomen seen in emaciation, etc. The appearance is as if an invisible rope was constricting the abdomen, dividing it into an upper portion which has a convex aspect centrally, and a normal lower part. Viewed laterally, the region of the "rope"

forms the apex of a vertically situated obtuse angle. It may be that it is an attempt of nature to limit the effects of the perforation to the upper portion of the general peritoneal cavity. The sign was present in my last two cases of ruptured ulcer, described later, and I was able to point out the phenomenon to the surgeon who administered the anaesthetic in each instance. The site of constriction is shown in the illustration as a dotted line. It represents the level of the lowermost limits of the costal arch, and may be termed the "infracostal line." In passing, it may

be mentioned that this line is below the level of the transpyloric plane, while it is above the level of the umbilicus. The ring of constriction corresponds to that portion of the anterior abdominal wall supplied by the ninth intercostal nerve, and is certainly due to muscular contraction.

The muscles involved are the two recti abdominis in front, with the external obliques, the internal obliques, and the transversales laterally. The contraction takes place at a situation where the abdominal wall is unsupported by bone on its anterior and lateral aspects, but it should be emphasized that the constriction does not apply to the whole of the ilio-costal space but to its upper part only. All of the muscles just mentioned share in the general protective reflex rigidity, but the extra contraction—forming the ring of constriction—requires some explanation. It cannot be solely due to the accentuation of one of the upper lineae transversae of the recti muscles, because the constriction extends beyond their limits into either flank. Of the three lateral muscles the transversalis is the most capable of producing a constriction because it is able to exert a direct transverse pull, whereas the oblique muscles in contraction by themselves would tend to straighten out any such tendency to a constriction.

The ninth intercostal nerve, supplying its segment of the muscles of the upper part of the anterior abdominal wall

travels in an almost transverse direction after leaving the shelter of its intercostal space.

In addition to the vagi nerves, the stomach and duodenum gain a sympathetic nerve supply from branches originating from the fifth to the eleventh thoracic spinal nerves, through the greater and lesser splanchnics to the coeliac plexus; and Cunningham's *Textbook of Anatomy* (third edition, p. 704) states that sympathetic nerve fibres "transmit to the cerebro-spinal system afferent fibres from the viscera."

In view of these factors—muscular and nervous—it is reasonable to assume that the powerful stimulating impulses of origin, the results of the perforation, are conveyed by the sympathetic fibres to the coeliac plexus and from these to the spinal cord when the whole nervous system is probably involved. Afferent impulses cause the wide pupil dilatation seen in shock. They reach the vasomotor centre with a resulting splanchnic dilatation, and they stimulate the motor nerve cells in the cord so that there is general rigidity of the anterior abdominal wall muscles.

ILLUSTRATIVE CASES.

Case 1.

P. J. L., aged 35, was admitted to the Royal Naval Hospital Ship *Plassy* for acute abdominal pain. Eighteen hours previously he had sudden overwhelming pain in the upper abdomen which doubled him up. He sweated, vomited blood, and thought he was going to die. For many years he had had epigastric pain coming on a quarter of an hour after food; there were no interscapular radiations of the pain, and more food did not give ease. He had never had melaena, a cough, or increased pain on inspiration; flatus had been passed recently, and micturition was normal. Upon admission his facial expression was anxious, he was collapsed and cyanosed. The pulse-rate was 112 and weak, the respirations 20 per minute, temperature 100° F., and the tongue furred and moist. There was a ring of constriction across the abdomen at the level of the lower margins of the ribs. He had board-like rigidity of the whole belly wall, there was dullness in both flanks, and the liver dullness was normal. The heart and breath sounds, pupils, knee-jerks, testes, and hernial sites were normal. Rectal examination showed no abnormality. A diagnosis of ruptured pyloric ulcer was made. This was confirmed at operation, and the patient made a good recovery from it.

Case 2.

P. C., aged 25, was admitted to the R.N.H.S. *Plassy* suffering from acute general pain in the abdomen of four and a half hours' duration. The pain at onset was sudden and appalling, he shouted out, sweated, and vomited. For a considerable time previously he had suffered from epigastric pain after food, with pain between his shoulder blades; there was no history of haematemesis or melaena. He attributed his ailments to obstinate constipation. During my investigation of the case he was constantly screaming out with pain and disturbed the other patients. His pulse-rate was 60 per minute, temperature 98° F., respirations 30 per minute, and a normal tongue. Abdominal respiratory movements were absent, but a transverse ring of constriction could be seen at the level of the lower margins of the costal arch. There was general rigidity of the belly wall muscles, also general tenderness of the abdomen. The remainder of the routine examination was negative. Operation confirmed the diagnosis of a ruptured gastric ulcer, and he made a good recovery.

PRIMARY AND SECONDARY IMPETIGO IN SOLDIERS.

BY MAJOR HENRY MACCORMAC, M.D., F.R.C.P.,
R.A.M.C.(T.C.).

ASSISTANT PHYSICIAN AND ASSISTANT SKIN PHYSICIAN,
MIDDLESEX HOSPITAL.

DURING April, 1917, out of a total of 1,786 patients admitted with skin complaints into — General Hospital it was found that 1,411 suffered either from primary impetigo, or from impetigo grafted upon some other condition. This secondary form may be so severe as to mask the underlying causal condition, leading to errors both of diagnosis and treatment, whereby disease is spread and cure delayed. In this paper four types or classes will be described. Special attention is directed to the mode of distribution, since this alone is usually sufficient to guide the observer to a correct conclusion.

I. TRUE IMPETIGO CONTAGIOSA.

Contrary to what might be expected, this condition, so tediously common in civil practice, rarely occurs among the troops in France. As is well known the causal agent, a streptococcus, gains entrance through some slight

abrasion or cut; in consequence the disease affects mainly those regions accessible to inoculation—the face, hands, and arms. The earliest lesion, a delicate vesicle, is soon ruptured and replaced by a superficial crust, aptly described as “stuck on.” The strikingly superficial position of these crusts and their irregular pattern upon the face enable impetigo contagiosa to be distinguished from impetiginized seborrhoea, to which it bears a close resemblance.

Treatment.—Removal of crusts is an essential first step in the treatment of all “impetigos,” otherwise the remedial agents cannot come into contact with the diseased tissues. This may be done with forceps, or more efficiently by boric fomentations or boric starch poultices. If, before fomenting, the lesions are smeared with liquid paraffin better results will be obtained. The naked sores should then be anointed with zinc ointment containing 1 per cent. ammoniated mercury; should this prove irritating, Lassar's paste may be employed instead, after washing with 1 in 1,000 perchloride lotion.

At times a rare form of impetigo contagiosa is met with in which the bullous phase persists throughout. The whole body becomes covered with blisters, small and large, and there may be constitutional symptoms. This condition is not pemphigus. If the blisters are opened, washed with 1 in 1,000 perchloride, and dusted with a powder of equal parts of starch and zinc oxide, to which is added 10 per cent. of boric acid, a cure is soon effected. Sheets and bed-clothing must of course be changed frequently to prevent the formation of new lesions by inoculation.

II. ECTHYMA.

Ecthyma is a deep or dermic form of impetigo contagiosa, and is most often seen on the legs and thighs. The fully developed lesion consists of a crust covering an ulcer full of matter. It is surrounded by an erythematous halo, the brightness of which indicates the active extension of the process; usually the marginal skin is undermined. This condition is induced by scratching to relieve itching caused by lice, or follows the friction and rubbing of garments soiled with mud or dirty water. Once started it spreads rapidly by autoinoculation. The sores can be distinguished from boils by the absence of a central hair follicle.

Treatment.—While the process is in a progression phase—as indicated by the brightness of the surrounding halo—obviously local antiseptic measures are useless, since neither liquid nor ointment can penetrate among the outlying cells where the streptococci are in active proliferation; their destruction is brought about by substances carried from within, and this is attained by frequent fomentations. To prevent infection the neighbouring skin should be washed over with 1 in 4,000 perchloride lotion before each fomentation. A preliminary removal of crusts and pus is, of course, essential. When the fading halo tells that active extension has ceased, antiseptics, such as half strength ensol, or 1 in 1,000 perchloride lotion, may be used. Sluggish sores can be painted with a solution of silver nitrate 2 per cent. in sweet spirits of nitre. In the last stages weak ammoniated mercury ointment or Lassar's paste should be employed.

III. IMPETIGO COMPLICATING SEBORRHOEIC ECZEMA.

The seborrhoeic diathesis appears to exist among the troops in France to an abnormal degree. Its influence is felt in the treatment of many skin diseases, especially scabies. In its most simple form seborrhoea is seen on the scalp as dandruff, and over the presternal and interscapular regions either as greasy red scaly patches resembling ringworm, or as a scattered follicular eruption. This mild form, relatively common, is not often brought to the notice of the medical officer. When the disease attacks the hairy regions of the face and scalp, it may take on a new and confusing aspect. The seborrhoea becomes eczemized—a process indistinguishable from eczema being grafted upon the pre-existing dermatosis. Nor does this usually end the matter. So susceptible have the affected tissues now become to streptococcal invasion that this germ almost invariably gains a footing, and then impetiginization is added to eczemization. In consequence, an appearance closely mimicking impetigo contagiosa is established. From this it can usually be easily

distinguished—first, because the scabs are distributed over the hairy regions, the beard, moustache, and eyebrows; secondly, by noting that the crusts are firmly attached, and are not of the “stuck on” type; and thirdly, by discovery of other seborrhoeic lesions on the back and chest. The ears rarely escape if the head and face are severely affected, and the process often extends along the auditory meatus, setting up a purulent discharge. This combination—a discharging ear with impetiginized seborrhoea of the auricle—tempts the observer to diagnose middle ear disease with impetigo contagiosa; the history of the two conditions is quite different, the running ear of seborrhoea following, not preceding, the skin eruption.

It is unwise as a rule to dogmatize in medicine, but he who treats every “impetigo” above the neck amongst soldiers in France as if it were an impetiginized seborrhoea will rarely be wrong, and will never do harm.

One other point should be referred to. Ecthyma and impetiginized seborrhoea may coexist, since the healthy skin can easily become inoculated with streptococci from the infected seborrhoeic lesions.

Treatment.—As the condition is an eczema rather than an impetigo, preparations such as calamine liniment should be employed. The formula is as follows:

Calamine	gr. xx
Zinc oxide...	gr. xv
Lime water	5 ij
Olive oil	5 j.

To bring it into intimate contact with the diseased skin scabs must first be removed, and, after shaving or close clipping, soaked lint applied to face and scalp; all crevices in and behind the ears are packed with soaked cotton-wool. Such treatment is either continued until cure, or towards the final stages Lassar's paste with 2 per cent. salicylic acid or ichthyol may be substituted. Should chronic fissures develop they may be painted with the silver nitrate solution already given. Running ears must be syringed frequently. Two complications often arise—boils and conjunctivitis. The former responds to fomentations and stock staphylococcal vaccines, the latter to frequent washing with boric lotion and eye drops of boric lotion containing 0.5 per cent. cocaine.

IV. IMPETIGO COMPLICATING SCABIES.

Uncomplicated scabies is seldom seen in France because the soldier rarely reports sick until his skin has become severely infected with pyogenic cocci; it is then easy to overlook the primary disease; for this reason men constantly arrive at base hospitals labelled I.C.T., eczema, boils, etc., who are the subjects of unrecognized itch. The distribution of the impetigo secondary to scabies is characteristic, the lesions being especially grouped over the lower buttocks, the elbows, and knees. Impetigo of the lower buttocks is invariably due to scabies, and in such cases a search will constantly reveal confirmatory lesions of the penis, wrists, or interdigital.

Treatment.—In infected scabies treatment is apt to be both long and tedious; medical officers should therefore aim at preventing this condition by constant inspection of the men under their care for the detection of the disease in its early stage. Even when secondary infection has taken place, it is essential in all but very exceptional cases to cure the itch by sulphur before attacking the secondary complications. Therefore treatment is started by a bath, three days' sulphur ointment, and a change of garments. Thereafter the ecthyma is dealt with as already described.

When secondary infection has been severe, a certain degree of dermatitis is an almost invariable accompaniment. It is troublesome because with it is associated sensations of itching of greater or lesser severity, which may be incorrectly thought to indicate that the acari have not been all killed. The following plan will be found useful: During the day Lassar's paste with ichthyol is rubbed over the affected skin, and at night calamine lotion is dabbed on it. It is perhaps unnecessary to insist that the ointment should never be applied to any lesion containing pus.

THE *Newspaper World* stated last week that 99 daily newspapers in this country and 615 weekly periodicals have now increased their prices.

Observations ON WAR SURGERY OF THE CHEST.

BY
CAPTAIN A. L. LOCKWOOD, M.C., R.A.M.C.,

AND

CAPTAIN J. A. NIXON, R.A.M.C.(T.F.).

(Concluded from p. 109.)

PART II. OPERATION.

In no other branch of war surgery is the technique of the operation more exacting, although the manipulations themselves do not require any exceptional dexterity.

A separate theatre is reserved for chest and abdominal operations and a uniform temperature of 80° is maintained. We have found it possible under all conditions, and we believe it is always possible, to maintain as perfect asepsis in a casualty clearing station as in civil hospitals. Cap, mask, gloves, and gown are worn by operator, sister, and assistant, and changed between each case. No one is allowed in the theatre unless wearing a sterile gown, and patients are brought into the theatre in blankets and pyjamas which have been put through the Thresh disinfectant the night before. The patient has been given omnopon-scopolamine (one ampoule) an hour before operation, and, if not sleeping, is given one-half ampoule half an hour before being taken to the theatre.

For operation the patient should be maintained with the injured side dependent. In the majority of cases the half-sitting posture is the most comfortable. A simple apparatus has been devised which allows free access to the injured side and which can be applied to any table.

If the patient cannot be placed with the injured side of the chest dependent, the lung should be grasped with forceps of the Collin pattern immediately on opening the thorax, and sufficient traction exerted to correct displacement of the mediastinum (Murphy).

The skin is prepared with picric acid (3 per cent.) in spirit; paravertebral anaesthesia is administered for two or three spaces above and below the wound, depending on the extent of the wound and the incision contemplated. To avoid delay, a local infiltration around, but at some distance from, the wound is employed. Novocain 0.5 per cent., potassium sulphate 0.25 per cent., in normal saline, prepared fresh and repeatedly autoclaved, is injected with a Gray's syringe (10 minims of adrenalin per ounce are added just before use). Gas and oxygen should be available to be administered while the hand is inside the chest or if the patient is restless; in the latter event a light nitrous oxide analgesia only is maintained.

The most serious chest cases can be operated upon with this type of anaesthesia—cases which would never be fit for a general anaesthetic, such as ether or chloroform. A more extensive, deliberate, and protracted operation can be undertaken with the minimum of shock to the patient under local anaesthesia combined with gas and oxygen. Respirations are deeper and more regular than with ether or chloroform, and the movements of the lung, mediastinum and diaphragm can be voluntarily controlled by the patient to some extent. The two-stage operation, which will be described later, is possible only with this type of anaesthesia. Post-operative restlessness, vomiting, retching, and coughing never occur, and this plays no small part in the success of the operation, especially in a busy unit where an attendant cannot always be at the bedside.

Never should ether or chloroform be used in chest surgery. The manipulative technique of chest surgery is extremely simple, but the utmost speed is essential. There is no doubt that unless primary union is obtained the patient's condition is made grievously worse by operation. Primary union will not result without bold and thorough excision of the wound area. After the track of the missile through the chest wall has been excised, the gloves of the operator are changed, the instruments used are discarded, the skin is again thoroughly cleansed with picric acid, and fresh towels are used. Rubber dam, if available, or towels are draped about the incision, in such a way as to expose no skin and the minimum of muscle, and fixed with clips. The patient and table should be entirely covered with sterile towels or an operating sheet.

When the position of the wound will permit, resection of the fourth rib from the mid-clavicular to the posterior axillary line furnishes the easiest access to the thoracic cavity. Resection of the rib must be wide enough to allow careful inspection of the cavity. Doyen's periosteal elevator and costotome are the instruments we have found best for resection of the rib. Tuffier's retractor is most satisfactory for obtaining a sufficiently wide opening. It is important, however, not to exert too powerful retraction on the chest wall, as the tendency to shock is thereby increased and the mediastinum unduly disturbed.

Immediately after opening the chest, rapidly mop out the thoracic cavity with gauze wrung out of hot saline carried on a long curved forceps of the Ochsner pattern. Unless there is fresh haemorrhage within the chest—which, of course, must always be attended to first—lacerations of the diaphragm must be first dealt with. Where access to the abdominal cavity through the chest is necessary the diaphragm may be freely incised without hesitation.

No wound of the diaphragm should be left unrepaired whether on the right or left side. Particularly when the missile has tracked through the diaphragm and lodged in the liver, the track through the diaphragm must be excised and the diaphragm incised widely enough to expose completely the track in the liver, and the missile removed. The track in the liver should be thoroughly cleansed out with a Volkmann's spoon, followed by swabs wrung dry out of saline and ether.

If oozing occurs, deep catgut sutures should be inserted with a blunt needle. As we have pointed out in an earlier paper on "Abdomens," missiles should not be left in the liver. A complete and thorough toilet of the track is always necessary; haemorrhage is not to be feared. The very low resistance of the hepatic tissues to infection makes it important to remove all sources of infection. Having dealt with the liver, close the diaphragm with mattress sutures of catgut on a blunt needle, except where the diaphragm is stripped from its parietal attachment. We do not believe it is advisable, or ever necessary, to suture the diaphragm to the chest wall (as suggested by Depage).

If the missile has passed through the diaphragm into the abdomen and an injury of a hollow abdominal viscus is suspected, it is wiser to deal with the abdomen after having closed the chest. After repair of the diaphragm, the lung, held with the Collin forceps, should be brought up to the opening in the chest (pneumopexy prolongs the operation and is never necessary), remove the missile or fragment of rib (if lodged in the lung), excise, thoroughly clean and suture the track or lacerations with mattress sutures of catgut, which should not be so tightly tied as to tear out on expansion. For repair of lung tissue a blunt round-bodied needle is used.

Partial lobectomy may be necessary, depending on the degree of laceration of the lung. Total lobectomy and, in one case, excision of both middle and lower lobes of the right lung has been necessary for acute malignant gas gangrene, but has not saved the patient's life. We have been struck by the rarity of finding an open bronchus at operation. For such a condition crushing and ligaturing with catgut is sufficient. It is essential that the visceral surface of the lung should in all cases be approximated, thus mechanically retarding effusion from damaged lung, and lessening the tendency for infective conditions to light up in the lung substance itself. Haemorrhage from the lung need not be feared.

All blood clot, pieces of cloth, fragments of bone, etc., must be carefully hunted for and removed from the thoracic cavity. The toilet of the pleura can better be performed by sponging (as in the case of the peritoneum) than by washing out. The last step before closing off the pleural cavity is to sweep round the chest wall, lung, mediastinum, and diaphragm systematically with swabs wrung dry out of hot saline, and, finally, with a swab wrung dry out of warmed ether.

The chest should always be closed, unless there is extensive gas gangrene of the lung tissue itself adherent to the chest wall.

Time should not be wasted in attempting to repair the parietal pleura in extensive wounds, as it can rarely be done; such pleura as remains can be caught up with the muscle sutures.

The chest must be hermetically closed with the first

layer of muscles, otherwise pocketing will occur, pleural effusion accumulate, the incision break down, and the operation fail. From the time the pleura is opened until it is closed, when the hands of the operator are not actually in the chest, the hole in the pleura should be covered by thick lint wrung dry out of hot saline. This closure is important, even if only for a moment at a time.

Careful approximation of the skin edges is necessary to ensure early and absolute primary union.

At one time we concluded the operation by aspirating the air from the pleural cavity with a Record syringe. From what we have seen of early post-operative expansion of the lung this step is unnecessary.

In some few cases we have left sodium bicarbonate solution in the chest (Witzel's method) and withdrawn it after eighteen hours. We have seen no benefit from its use either in providing an alkaline field to inhibit bacterial growth or in aiding expansion of the lung. A wide gauze dressing with mastisol or "aeroplane dope" reduces the tension on the sutures and binds the layers of the chest wall so as to prevent oozing and pocketing. A binder made of 7 in. adhesive plaster (tying over the dressing) is valuable to retain the dressing, as well as to relax tension on the sutures and leave the sound side of the chest free for expansion; the latter is extremely important.

On completion of the operation the patient should at once be supported in a semi-recumbent position inclined to the injured side.

The "two-stage" operation is indicated in the type of case with the entrance and exit wounds far apart—front and back or lateral—where gross lesion of the bone, or extensive destruction of the tissues, necessitates an extensive operation of both wounds. In such a case, enter the chest through the wound which allows freest access to the pleural cavity and to the part probably damaged. After carrying out the operation as outlined above, leave the patient on the table in a comfortable position, surrounded by hot-water bottles. Give intravenous sodium bicarbonate or blood transfusion as required, administer sodium bicarbonate and glucose, 8 oz., per rectum. Half an ampoule of omnepon should be given if the patient is at all restless. After one or two hours, deal with the other wound. For the second stage, a further paravertebral anaesthesia is frequently not required—merely local infiltration about the site of the incision.

Lacerations of the diaphragm on both sides should be dealt with by this "two-stage" operation.

There is a percentage of cases in which the treatment between the two stages will recuperate the patient to such a degree that he is fitter for the second stage than he was for the first.

Injuries of the heart or pericardium can be best dealt with by a parasternal flap of the fourth and fifth, or the fifth and sixth, costal cartilages, depending on the probable site of the lesion (the divided cartilages unite rapidly), and this route, in addition, gives free access to the pleural cavity.

Where the missile has passed across the pleural cavity and lodged in the mediastinum, especially high up, it is wiser to enter the mediastinum through the sternum. The missile should be removed, its bed and track thoroughly cleaned, and the pleural opening closed to prevent any leakage from the mediastinum into the pleural cavity. This serves a double purpose—it obliterates a pocket in which pleural effusion might accumulate, and shuts off from the pleural cavity a source of reinfection. It is difficult to deal with the mediastinum through the usual costal incision.

Gross lesions of the parietes under the scapula are always difficult to reach. It is possible to deal with such wounds from either vertebral or axillary border—winging or fixation of the scapula never results if movements are started early enough. Trephining of the scapula is neither advisable nor necessary.

Extensive injuries to the spinal column when associated with wounds of the thorax, even if the cord is not damaged, are usually rapidly fatal.

In the gross wounds of the thorax which cause death on the battlefield, or in the advanced dressing stations, injuries to the phrenic nerve are probably frequent owing to its anatomical situation. We have frequently seen a "flapping" diaphragm under the screen where we pre-

sumed that the phrenic nerve was injured. In one case a diagnosis of hernia of the stomach through the diaphragm was made. At operation the diaphragm was found to be exceptionally high. Death occurred thirty-six hours from the time of receiving the wound; autopsy revealed a phrenic nerve almost completely severed.

A pin-head perforation of the descending aorta, still bleeding after twenty-four hours, was discovered at operation in one fatal case. In four cases leakage from the thoracic duct has been diagnosed. Rapid and extreme emaciation characterized all four cases. Death ensued within twelve to twenty-seven days. In all of these cases the wounds, apart from that of the duct, were so extensive that no surgical interference with the duct could be undertaken.

POST-OPERATIVE TREATMENT.

The post-operative treatment of chest wounds demands greater attention and more minute daily observation of the patient than wounds of any other region.

The patient is kept at rest in the position he finds most comfortable; this is usually semi-recumbent at first, later he is raised to a semi-sitting posture. The patient's position is changed frequently, but the injured side is always kept dependent. If cyanosed, oxygen passed through warm brandy is inhaled. Undue restlessness is not to be allowed; omnepon in small doses is freely administered, if required. Every means of counteracting acidosis is employed. Glucose and sodium bicarbonate (5 per cent. each) are administered per rectum by continuous drip for forty-eight hours (as a rule, about 5 pints can be absorbed in this way in twenty-four hours). Sodium bicarbonate (80 to 100 grains per diem) is given by mouth until the patient is absolutely convalescent. Barley sugar is allowed *ad lib.* The patient sips a 2 per cent. solution of glucose (8 oz. every two hours). Forced and frequent feeding is essential. The bowels are kept acting freely, as an overloaded colon is a source of great discomfort to the patient. Stimulants of all kinds, such as camphor, strychnine, caffeine, etc., are avoided; brandy is given if the patient is an habitual user of it.

Chest cases should be nursed in the open air if possible. Aspiration is carried out as a routine eighteen hours after operation and at the end of the third day. Exploration of the chest is performed at frequent intervals whenever an accumulation of even small quantities of fluid is suspected, and fluid, if found, is removed by aspiration. Fluid must not be allowed to collect after operation. Physical signs are misleading, and nothing but repeated use of the exploring syringe and aspirator, aided by x-ray examination, will keep a chest safely emptied of fluid.

CONCLUSIONS.

1. Chest cases are as urgent as abdominal cases and should be evacuated direct to the casualty clearing station as soon as they can stand the journey.
2. The better the evacuation from the battlefield, and from the advanced medical units, the severer is the type of case that reaches the casualty clearing station. Thus deaths occur in the casualty clearing station which would otherwise take place further forward. This was particularly noticeable in our "Z" group.
3. The percentage of severe chest wounds reaching the casualty clearing station is very much greater when the casualties are principally due to shelling and bombing, especially of the back areas, when the casualty clearing stations are the nearest medical units.
4. Cases of traumatepnoea should be closed (preferably by suture) at the advanced dressing station, or even, if possible, at the regimental aid post.
5. All chest cases should be given morphine early.
6. Active resuscitation must be carried out at the casualty clearing station immediately upon admission. The majority of severe chest wounds require blood transfusion.
7. The value of x-ray examination in chest surgery cannot be over-estimated.
8. The complete intrathoracic operation is a serious one and should not be lightly undertaken.
9. Local anaesthesia, combined with gas and oxygen (if required), should be employed in chest surgery.
10. Speed and absolute asepsis are essential to success.
11. The operation must begin with *excision in toto* of the wound and end with hermetical sealing of the thorax.

12. No fluid must be allowed to collect in the pleural cavity after operation.

13. Resection and drainage should be a late resort, and are rarely necessary, never unless severe constitutional symptoms of infection are present.

14. Non-operated cases should be treated precisely as post-operative cases.

15. Men who have been exposed to asphyxiating gases bear chest wounds badly.

16. At certain seasons bronchopneumonia is a complication greatly to be feared. (Vide autopsy reports.)

In no class of surgery is team work so essential to success. The surgeon, physician, radiographer, and anaesthetist should work hand in hand. The theatre sister should be particularly quick and methodical, knowing each step in the operation, and avoiding delay by having everything prepared in advance and at hand. A post-operative sister, who has had long experience in the nursing of these cases, is a most important member of the team.

ILLUSTRATIVE CASES.

Appended are brief accounts of six cases operated upon. These have been selected as representative examples of various types of injury and the operations performed.

CASE I.

Pte. D., aged 34. Case of traumatopnoea, missile lodged in right lung, comminuted fracture of fourth and fifth ribs. Operation. Gas infection of pleural cavity treated by repeated aspiration.

Admitted September 18th, 1917. On arrival the patient was in a condition of extreme collapse. Resuscitation for six hours.

Operation (ten hours after wound).—Omnopon-scopolamine; anaesthesia paravertebral and local. Wound, situated in right mid-axillary line, widely excised. Two inches of fifth and four inches of fourth rib removed; large haemothorax; track admitting two fingers entering outer and upper aspect of lower lobe extending to inner and posterior border. Contusion of lower half of injured lobe. Missile removed. Track thoroughly excised and closed with mattress sutures of catgut. Pleural cavity swabbed dry. Chest closed in layers.

Progress.—Aspirations were made at the following periods after operation:

18 hours: 7 oz. blood-stained serum.

19th day: 9 oz. thick pus. Cultures: aerobic sterile; anaerobic gas producers.

23rd day: 7 oz. thick greenish pus, distinct odour. Cultures: aerobic, streptococci; anaerobic, *B. perfringens*.

27th day: 1 oz. thick pus. Similar cultures.

33rd day: 4 oz. dark-red stinking gas gangrene pus. A rush of gas escaped through trocar on insertion.

Explored on the forty-fifth day: No fluid or gas found. On the sixty-second day the patient got out of bed. He remained quite well, was very active doing light duty in the ward. After operation the patient expectorated blood-stained sputum, followed by thick nummular pus. Expectoration stopped after twenty days. This is a case of a type which three months earlier we should have treated by immediate resection and drainage on the result of the thirty-third day's aspiration. He was evacuated on November 20th, 1917.

It is cases such as this that persuade us that the ability of the pleura to deal with infection is very great, and that resection and drainage is an operation rarely necessary.

CASE II.

Private B., aged 19. Case of missile traversing right chest (haemothorax), mediastinum, and lodging in apex of left ventricle of the heart.

Admitted August 7th, 1917. Entry wound in right posterior axillary line. Closed haemothorax (right). Missile located by x rays on left side, presumably behind pericardium. There was no cardiac irregularity, and no signs of air or fluid in the pericardium. Haemothorax was aspirated on the fifth day (35 oz., non-infected).

Operation (fourteen days after wound, on account of continued pyrexia and missile being retained).—Omnopon-scopolamine; paravertebral and local anaesthesia (no gas and oxygen). Chest opened by parasternal incision through fourth, fifth, and sixth cartilages on left side. The missile was searched for behind the pericardium, but not found. No haemothorax on left side. On palpating the pericardium and heart the missile was felt in the heart muscle. The pericardium was widely opened, and the missile (quarter of an inch square) found lying superficially in muscle on the posterior aspect of the apex. No fluid in pericardium; thin, non-adhesive, sero-fibrinous film covering visceral and parietal pericardium. Unfortunately, owing to difficulty of accurate localization by x rays of a missile in the heart (especially at the apex, where movements are at their maximum and the limits of the pericardium are so close), the pleural cavity had been unnecessarily searched. Even the gentlest attempts to grasp the heart laterally, or to raise its apex (on catgut sutures), caused it to stop beating. As fourteen days had elapsed since wounding, and there was no inflam-

matory process round the missile, it was judged wisest to leave it *in situ*. The pericardium and chest were closed. During handling of the heart and pericardium the patient complained of no pain or distress, either cardiac or respiratory, although local anaesthesia only was used.

Progress.—Uninterrupted recovery. No cardiac irregularity was observed after operation. The patient was out of bed three weeks before evacuation, doing light duty in the ward. He was evacuated on November 4th, 1917.

CASE III.

Pte. McC., aged 19. Case of traumatopnoea (eighth space, left, in posterior axillary line) with missile and fragments of rib embedded in diaphragm.

Admitted August 27th, 1917. Condition fair, but patient complained of acute pain in epigastrium. Respiration typical of diaphragmatic injury. X rays showed "stutter movement" of diaphragm and large shell fragment probably impacted in diaphragm.

Operation (immediately after admission; eight hours after wound).—Omnopon-scopolamine; paravertebral and local anaesthesia. Gas and oxygen while hand was inside thorax. Haemothorax cleared. Lower lobe of left lung lacerated. Missile, $2\frac{1}{2}$ in. by $\frac{1}{2}$ in. by $\frac{1}{2}$ in., found lodged in diaphragm. Two sharp spicules of bones and missile impacted in highest part of diaphragm, apparently causing the pain. Laceration ($\frac{1}{2}$ in.) of diaphragm close to costal border, and a second laceration where the missile was imbedded. Both lacerations of diaphragm and laceration of lung sutured. Chest closed. Immediately after operation the pain was relieved.

Progress.—Lung in total expansion within twenty-four hours. Four days after operation temperature rose to 104° ; pulse 106; respirations 26. In spite of the pyrexia drainage was not considered, but on the tenth day, as pyrexia continued, aspiration was performed—1 to 2 ounces of perfectly sweet, blood-stained serum found. The temperature rose to 102° on the twenty-fourth and again on the twenty-eighth day. Nevertheless he made an uninterrupted recovery. He was out of bed on the thirty-ninth day, and did light duty in the ward for one month after. He was evacuated on November 4th, 1917.

CASE IV.

Sgt. B., aged 39. Case of penetrating wound of chest with perforation of diaphragm; missile lodged in liver.

Admitted September 11th, 1917 (four hours after wound). Condition, grave shock, resuscitation for three hours.

Operation.—Omnopon-scopolamine; paravertebral and local anaesthesia. Gas and oxygen while hand was in thorax. Small open wound in tenth space (right) in anterior axillary line and chipping of ninth rib. Wound excised *en masse* into pleural cavity. Incision extended; four inches of ninth rib removed. Small haemothorax with some blood clot. Lung two-thirds collapsed. Perforation in diaphragm the size of a threepenny bit. Active bleeding through hole in diaphragm, believed at first to come from diaphragm. Wound of diaphragm excised and incised extending one inch back and front from wound. Very small perforation found in liver, bleeding freely and suggestive of arterial blood. Track cleaned out with Volkmann's spoon. Incision made in track wide enough to admit index finger. Missile (high explosive fragment $\frac{1}{2}$ in. by $\frac{1}{2}$ in.) found three inches deep and removed. Bed of missile thoroughly cleaned with Volkmann's spoon and swabs wrung out of hot saline, finally one swab wrung out of warm ether. Track closed with four deep catgut sutures. Some blood clot lying below the diaphragm. Subphrenic space and right peritoneal cavity swabbed dry. Diaphragm closed with catgut sutures. Pleural cavity swabbed dry. Chest wall closed.

Progress.—Uninterrupted recovery. Lung in complete expansion after twenty-four hours. On aspiration, 5 oz. sterile serum. Out of bed fifteen days after operation. Evacuated November 20th, 1917. Doing light duty in ward for three weeks before evacuation.

CASE V.

Gunner C., aged 31. Case of penetrating chest wound; haemothorax; laceration of diaphragm, liver and kidney, with hernia of colon.

Admitted September 27th, 1917. On arrival at casualty clearing station he was moribund. Active resuscitation; heater-bed, sleep (omnopon), intravenous sodium bicarbonate (2 per cent.) 20 ounces. Rallied very slowly. Blood transfusion 600 c.cm., with Kimpton-Browne tube. (As this patient belongs to No. 3 blood group there was delay in finding a donor to correspond.)

Operation (6 hours after admission).—Prepared and taken to theatre directly after blood transfusion, condition being much improved. Pulse-rate 130 to 140; blood pressure 85; respirations rapid; right chest not moving; entire abdomen rigid. Large entrance wound, admitting three fingers (not sucking), just to right of body of third lumbar vertebra. Dirty jagged exit wound admitting three fingers over the costal cartilage of the ninth rib (right) in anterior axillary line. Colon herniating through exit wound, gangrenous patch size of 1 franc piece with half-inch laceration. Anaesthesia, paravertebral and local. Incision from edge of third lumbar vertebra to cartilage of ninth rib. Excision *en masse* of entry and exit wounds with deep muscle of back. Gangrenous patch in bowel excised and opening closed with Czerny-Lembert sutures of linen thread. Colon replaced in peritoneal cavity. Chest entirely full of clotted blood. A widely open laceration of the diaphragm, 5 in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. from parietal attachment. Lung almost completely collapsed. Blood

clot removed. Pleural cavity swabbed clean. Diaphragm sutured with catgut. Laceration of outer and lower border of liver admitting three fingers, but liver not bleeding. Peritoneal cavity swabbed dry, peritoneum closed. Right kidney split across beyond repair. Nephrectomy. Incision closed except for small two-way catheter left in para-renal space for forty-eight hours. The operation was carried out entirely under local anaesthesia—no gas and oxygen. An almost continuous conversation was carried on between the patient and the anaesthetist during the whole operation.

Progress.—On account of difficulty in finding another donor of his blood group, sodium bicarbonate was given intravenously at the end of the operation. Recovery was complete and uneventful. The lung was in almost complete expansion in less than forty-eight hours. Although the patient remained perfectly well and had never complained since operation, on the twenty-first day an increasing area of dullness was noted in right chest. On exploration, fluid was found and 48 oz. of thin serum, of the colour and consistency of olive oil, was withdrawn by aspiration. Cultures, staphylococci. Explored ten days later—no fluid found. He was evacuated on November 20th, 1917, perfectly well.

CASE VI.

Sgt. G., aged 32. Case of chest crushed by falling in of dug-out. Subscapular fracture of four ribs (third, fourth, fifth, and sixth) on left, and two ribs on right side. Small haemothorax or haematoma of lung (left). Detained at advanced dressing station for twenty-four hours.

Admitted September 6th, 1917. On arrival at the casualty clearing station he was deeply under the influence of morphine, but coughing and complaining of intense pain in the left scapular region. Kept submerged with omnopon for five days. Each day an effort was made to discontinue omnopon, but violent coughing and pain made this impossible. X rays showed overriding of fractured ends of fourth, fifth, and sixth ribs (left side) to the extent of nearly three inches; the third rib on left, and the two ribs on right showed clean fractures. Effusion in left pleural cavity increasing. It was decided to undertake this most serious operation because it seemed impossible to relieve the pain otherwise, and the patient's condition was becoming rapidly worse.

Operation (September 9th).—Omnopon-scopolamine; para-vertebral (six spaces) and local anaesthesia. A curved incision was made from the second to the seventh intercostal space (left), internal and parallel to the vertebral border of the scapula. Pleura found open in the fourth, fifth, and sixth spaces. Three inches of each of these ribs removed. Haemothorax (3 to 4 oz.) cleared out. Left lung in almost total expansion, with its entire posterior surface excoriated, and showing minute petechial haemorrhages in its substance. Pleural cavity swabbed dry. Incision closed. No gas and oxygen given.

Progress.—Aspirations were made at the following periods after operation:

- 18 hours: 10 oz. blood-stained serum.
- 11th day: 1 oz. blood-stained serum haemolysed.
- 14th day: 12 oz. blood-stained serum with streaks of pus.
- 19th day: 10 oz. thick, foul-smelling pus. Cultures: aerobic, staphylococci; anaerobic, gas producers.
- 24th day: 20 oz. thick, foul-smelling, yellowish-green pus. Cultures: staphylococci and gas producers.
- 28th day: Explored; no fluid found.
- 31st day: 7 oz. fluid, more serous and sweeter.
- 33rd day: 6 oz. thin yellowish serum, sweet.
- 36th day: 4 oz. yellow serum, streaked with pus, sweet, sterile.
- 42nd day: 8 oz. yellowish-red serum, sweet. Cultures: aerobic, sterile; anaerobic, gas producers.
- 45th day: Explored; no fluid found.

Convalescence uninterrupted. He was out of bed on the seventieth day, and evacuated on November 20th, 1917.

As the hospital had to be cleared, this patient, together with two others, was evacuated before being put on light duty. All aspirations were made in practically the same place in the left mid-axilla. They appeared to empty a small localized collection. Otherwise the lung was in complete expansion eighteen hours after operation. Although this case was operated on under the most rigid asepsis and there was not even an abrasion of the skin, bacteria gained entrance to the pleural cavity. The wound itself healed by first intention. Immediately after operation the patient lost his pain and it did not return. The success of this operation, in spite of a subsequent empyema, suggests that more radical surgical measures might be adopted in similar cases in civil practice. The rapid recovery by aspiration from an empyema infected by aerobes and anaerobes demonstrates that repeated aspiration should be resorted to before considering resection and drainage. The mortality of the latter operation in chest wounds at casualty clearing stations is nearly 50 per cent. (Elliott).

THE School of Maritime Hygiene at Naples has, by permission of the Italian Minister of Marine, assumed the name of the late Professor Alessandro Pasquale, colonel in the medical service of the Italian army, its founder and organizer. He made it a centre of higher study in hygiene and tropical pathology for the special instruction of medical officers of the navy.

A PRELIMINARY NOTE ON THE TREATMENT OF INFECTED HAEMOTHORAX.

BY

LIEUT.-COLONEL J. F. DOBSON, M.S., F.R.C.S.,
R.A.M.C.(T.F.).

SURGEON, LEEDS INFIRMARY.

THE surgical treatment of infected haemothorax depends, as in other infections, on the stage at which the case is seen and the necessity for intervention recognized. Resection of rib, evacuation of fluid and clots, the removal of foreign bodies when possible, and immediate closure of the pleural cavity, is ideal, and is being more and more widely adopted at the casualty clearing stations. It is only applicable in the earliest stages of the infection, and at present the published records leave some doubt as to the results and the number of cases in which a secondary drainage has to be established. Experience of men detained on the lines of communication as unfit for further transport shows that when recurrence of symptoms arises these patients very rapidly become seriously ill.

A high degree of surgical judgement is required in the selection of cases of infected haemothorax suitable for immediate closure. As experience increases, and facilities for early operation are improved, we may expect much better results; but at the present time there are a large number of cases which cannot be treated in this way—the infection has passed beyond the contents to the walls of the pleural cavity.

I have had some opportunities of treating cases of this kind by a method of irrigation through a special cannula (Fig. 1), which appears to be of promise. The curved silver cannula has no terminal aperture, and is perforated with twelve small holes. It is employed in the following manner:

FIG. 1.

A sufficient opening is made into the chest by resection of a length of rib, preferably the eighth. Tuffier's spreader is then inserted, the pleural cavity wiped out, and perhaps a foreign body is removed or other complication dealt with. A point on the chest wall towards the upper limit of the cavity is selected where the cannula may most conveniently be introduced. This is usually in the third or fourth space, about or just external to the mammary line; a small incision is made through the skin, and the cannula pushed through the intercostal muscles into the

FIG. 2.

chest. The tip of the cannula should point outwards and downwards, and the instrument is fixed in position by two sutures to the skin. The original incision is then closely sutured around a tube which may be long enough to reach into a bottle of antiseptic fluid (Fig. 2). The tube of a Carrel ampoule is then attached to the cannula, and

the cavity irrigated every two hours. Hitherto I have used eusol, but no doubt other solutions will be as efficacious.

If the working of the cannula is tested in the *post-mortem* room, it will be seen that a fine spray of fluid is thrown in every direction on to the lung and chest wall. The irrigation causes no distress; a full ampoule of fluid has been run through the pleural cavity at one dressing without any inconvenience to the patient. As the lung expands the point of the cannula is pressed against the chest wall and causes some pain; it should then be removed. For this reason it is desirable to insert it at some little distance from the anterior and upper limits of the cavity, otherwise it may have to be taken out before the infection is controlled.

It is too early yet to speak of actual results. The impression I have gained from a limited number of cases, and these all late, with severe infection, is that the infection is quickly controlled, that the lung expands well, and that the general condition of the patient improves very rapidly. Certainly at present the results of drainage of a badly infected haemothorax are not good. (I refer now to cases which cannot be treated by immediate closure.) Many cases discharge for long periods, and only heal after much falling in of the chest wall, or after wide resection of ribs—in any case with a greatly damaged and comparatively useless lung, and a deformity of the chest and spine.

I have not yet had a case in which there seemed any necessity for secondary closure of the chest. If the lung did not expand after the pleural cavity had been rendered sterile, or approximately so, by irrigation, I should not hesitate to reopen the wound, free the adherent lung, and close the chest.

GUNSHOT INJURIES OF THE ELBOW-JOINT: TREATMENT BY EARLY EXCISION.

BY

CAPTAIN W. MOIR SHEPHERD, M.D., CH.B. EDIN.,
F.R.C.S. EDIN., D.T.M. and H. CANTAB., R.A.M.C.

INJURIES inflicted in the region of the elbow-joint of necessity vary with the nature of the missile, the degree of sepsis, and the amount of damage to bone and soft parts.

The experience of civil practice in connexion with fractures involving this joint serves to show how even a slight injury may interfere with and cause permanent disability and restriction of function. The ultimate results of injuries to the elbow-joint caused by gunshot wounds cannot be regarded as satisfactory, as in the majority of cases there is complete ankylosis, and not always in the most favourable position. Several such cases have recently come under observation at the base. Even if the wound remains aseptic, bony outgrowth will in the long run inhibit movement to a considerable degree. It is, however, the regrettable experience of most surgeons that comparatively few gunshot injuries remain aseptic, and this is particularly true in the case of joints.

When the bones are badly comminuted, especially the lower end of the humerus, and with it perhaps also the olecranon process of the ulna, results are deplorable—sepsis spreads in the surrounding parts, which become oedematous and swollen, the synovial membrane is infected, drainage is difficult and unsatisfactory, and the patient rapidly shows signs of septic absorption. Whatever method to combat infection be undertaken the results are the same—the bone goes on necrosing, and accurate apposition of fragments is out of the question, a long and tedious illness results, and one not devoid of risk to the patient—risk of both life and limb.

Primary excision of the elbow for tuberculous disease, fracture dislocation, and the like yields good results, and it would therefore appear feasible that equally good results might be obtained by early excision of wounded joints. The degree of sepsis in the surrounding tissues forms no contraindication to immediate excision—in fact, experience has shown that the free drainage immediately provided by the excision of the joint is coincident with a rapid fall in pulse and temperature, and the patient makes strides towards recovery, and is soon able to be up and about.

The question arises, How much bone is to be removed to secure a satisfactory new joint? but this, of course, will largely depend upon the nature of the primary injury.

A large number of cases of gunshot wounds of the elbow-joint with little or no damage to heads of radius or ulna have passed through my hands at a base hospital. In an early series of cases the classical excision of the joint was performed, removing the humerus just above the level of the epicondyle, the whole of the head of the radius and ulna at the same level, but, as was to be expected, movement was long in returning, and the forearm muscles had to be re-educated. A more satisfactory functional result can be obtained by removing less bone and interfering less with muscle attachments.

In a late series the lower end of the humerus was removed above the level of the epicondyles and rounded well off, preserving the radius and ulna intact and not interfering with the attachment of triceps to ulna if the latter was not already damaged. The incision employed was the angled incision of Kocher, beginning at the lateral epicondylar ridge two or three fingerbreadths above the joint level, pressing vertically down to the head of the radius and thence along the lateral border of the anconeus to the dorsal border of ulna about three inches below the tip of the olecranon, and finally curving medially over the ulna. In certain cases the incision had to be modified to suit the wound existing, but as far as possible the angled incision was employed to avoid damage to important structures.

The treatment naturally varied, depending upon the degree of sepsis present. If severe the wound was left widely open and treated with eusol gauze or after the method of Carrel-Dakin, the arm being fixed to a splint at right angles until sepsis subsided and the surrounding parts returned to normal. In milder cases the wound was partially closed with sutures, while the last few cases which came to the base early were excised, bipped, and closed after the method of Rutherford Morison, with excellent results.

The splint is left off as soon as the wound has healed sufficiently and the arm supported with a sling, the patient being encouraged from the first to use his wrist and fingers. At night the arm is extended on a pillow or fixed to a straight or widely-angled splint, if desirable.

The results, even in very septic cases, were surprising, the wounds cleared up rapidly, and the patient was able in all cases in the series to be out of bed at an early date, and movement was encouraged by the end of the fifteenth to eighteenth day. One patient at the end of a month could flex and extend his elbow as well as pronate and supinate his forearm and only a small healing sinus remained. The earlier the excision is performed the more certain is the patient to have a good and serviceable arm with free movement.

The conclusions arrived at from observation of fourteen cases are as follows:

1. Excision of the elbow-joint in gunshot wounds offers the patient the best chance of combating the infection and of a rapid recovery with a movable joint.
2. If excision can be performed without the removal of the heads of radius and ulna, the results are better and more quickly attained.
3. Where possible the triceps insertion should always be preserved.
4. The earlier the excision is performed the shorter is the illness and more perfect the result.

TWO CASES OF ABSCESS OF TESTIS DUE TO BACILLUS COLI.

By W. GIFFORD NASH, F.R.C.S.

THE two cases related in the following notes illustrate a comparatively rare affection and one which has received very scant notice in works on diseases of the genito-urinary organs.*

CASE I.

On February 17th, 1913, I saw, with Dr. L. Gifford Nash of Turvey, Beds, a gentleman suffering from acute cystitis, following a wetting whilst shooting in Ireland. The urine was acid, and contained a fair amount of albumin with a deposit of pus and blood. The Clinical Research Association reported that it also contained a colon bacillus of the *Bacillus lactis aerogenes* type. Under urotropine the cystitis soon cleared up.

* A very complete description of a similar case was given in the *Lancet* of October 4th, 1913, by Mr. W. P. Bonner.

In May, 1913, the patient had a mild attack of epididymo-orchitis whilst staying in Sussex, and also suffered from boils, for which he was treated with a vaccine.

On December 13th, 1913, he was admitted to the Bedford Nursing Home under my care, suffering from high fever and swelling of the right testis and epididymis. The urine contained pus. On December 24th an abscess of the testis was opened, and the body of the testis, which had sloughed, was removed.

On January 13th, 1914, the epididymis was excised and sent to a pathologist, who found a coliform bacillus resembling the *B. pseudo-asiaticus* of Castellani.

A vaccine was prepared and used for a considerable time. Dr. L. G. Nash informs me that there have been occasional mild attacks of swelling of the left epididymis, and that *Bacillus coli* is still present in the urine.

CASE II.

On August 11th, 1917, I saw with Dr. Harrison of St. Neots a married man, aged 27, suffering from acute swelling of the left testis and epididymis. His history was that whilst serving in the army he had an acute attack of swelling of the right testis on May 7th, 1917. About May 20th the swelling was punctured and pus found. On June 1st castration was performed, and he was told that he was suffering from tuberculous disease of the testis. There was no history of urethritis. He left hospital on July 28th, and was discharged from the army.

On July 31st he returned home to his wife and sexual intercourse took place. On August 2nd he had pain in the left testis and slight swelling which progressively got worse. The swelling of the testis was preceded by frequency of micturition.

When I saw him on August 11th there was redness of the left side of the scrotum, and swelling and tenderness of the left testis and epididymis. From the history of the acute attacks in May and August I diagnosed an infection with *Bacillus coli*, and as he had lost his right testis I advised incision of the left testis with a view to letting out the infected products and saving some part of the testis. The patient was removed to the Bedford Nursing Home, and on August 12th I incised the scrotum and also the testis and epididymis. The testis had commenced to slough. Pus from the testis was sent to Dr. Eastes's pathological laboratories, and it was reported that the material contained the *B. coli* and *proteus*. A vaccine was made and twelve doses were given.

On October 25th Dr. Harrison reported that the wound had healed, the testis was atrophied, and the sexual functions were a good deal impaired.

REMARKS.

The cases related were both due to infection of the testis and epididymis by bacilli of the colon type. It is probable that the infection gained entrance along the vas deferens, as in both cases the inflammation of the testis was preceded by bladder disturbance.

In the diagnosis of this condition we must think of acute gonorrhoeal epididymitis, acute tuberculosis of the epididymis, and acute torsion of the testis. In both cases the occurrence of gonorrhoea was denied, and there was no history of any urethral discharge. Gonococci were not found in the urine or in the epididymis and testis. Further, gonorrhoeal epididymitis very rarely suppurates. In neither case was there any evidence of tubercle in the genito-urinary tract, and the acute onset and rapid sloughing of the testis did not resemble tuberculous disease. Torsion of the epididymis was not present in either case.

As to treatment, I believe that the use of a vaccine and early incision of the inflamed structures give the best chance of saving the testis.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

REFERRED SYMPTOMS IN COMMENCING INGUINAL HERNIA.

I HAVE examined 18,000 English and German soldiers, and have been much struck with a common symptom amongst a considerable number—namely, pain in the region of one costal margin, increased tension of the upper segment of one or other of the rectus muscles, a general feeling of discomfort in the upper part of the abdomen without any definite physical signs of indigestion or other intra-abdominal trouble. If such a case presents itself, and if the patient has been standing or walking for a couple of hours, and equal pressure is applied over both internal abdominal rings (with the thumb of each hand), the facial expression will show uneasiness, or actual pain may be localized over the ring on the same side as the abdominal pain for which advice was sought. Over and over again a cure of the symptoms has been obtained by the application of a lightly fitting truss.

The anatomical reasons to my mind are quite plain. The nerve supply of the intestines is from the solar plexus, situated chiefly round the crura of the diaphragm, and that of the abdominal muscles is through the lower intercostals.

The diagnosis to be correct must not depend upon asking if there is pain in a particular locality in the iliac region. If there is a facial expression of discomfort, or actual pain, ask where. The answer will mention the ring on the same side as the abdominal symptoms. This method of examination will exclude malingerers, and any leading question will cause in all probability a false diagnosis.

W. B. COSENS, Captain R.A.M.C.,
M.O. i/c Prisoners of War Hospital, Dorchester.

A CASE OF PORENCEPHALY.

R. I. M. was admitted into the Jamaica Government Lunatic Asylum on April 13th, 1914, with a history of epilepsy. She was a well-developed woman, aged 37, with right-sided hemiplegia. The right upper limb was flexed at the elbow, wrist, and finger-joints, a very limited range of movement being left. The muscles of the limb were quite wasted. The right lower limb was equally affected as regards wasting and limitation of movement. She could neither spit nor whistle, and saliva was continually dribbling from her mouth. She was suicidal but not dangerous. There was no instrumental delivery at birth. She began to have fits when 16 months old. The paralysis was noticed at the time, and she attended school for a period, but, owing to the severity of the fits, had to be taken away. No one of her relatives has been insane.

During her stay in the institution she had fits periodically, and suffered from recurrent attacks of pellagra, otherwise she enjoyed fairly good health. For six months before her death she had fits, but she gradually began to get very emaciated, and had to be confined to bed up to the day of her death, September 2nd, 1917.

Post-mortem examination revealed the following: The skull was very thick, dense, and heavy. The dura mater was thickened, fibrous, but not adherent to the calvarium. The pia arachnoid was opaque and oedematous. *Brain*: There was a notable disproportion between the two sides; right hemisphere—simple convolitional pattern, congested, no wasting; left hemisphere—simple convolitional pattern, pale, general wasting. On section from the anterior to the posterior pole there was a well-marked cavity containing straw-coloured fluid which was not turbid. When the fluid was let out the cavity was smooth, there being a complete absence of the basal ganglia or any other vestige of brain matter. Lying across the floor of the cavity were remnants of the choroid plexus. There was an excess of cerebro-spinal fluid. The brain weighed 895 grams. Examination of the cerebellum, pons, and medulla showed nothing abnormal. No morbid changes calling for special note were found in any of the other viscera.

For permission to publish particulars of this case I am indebted to Dr. D. J. Williams, Medical Superintendent.

H. E. BOND, M.D., Dip. Psych. Med. (Can.),
L.R.C.P. and S. Edin.,

Junior Medical Officer, Lunatic Asylum, Jamaica, B.W.I.

Reports of Societies.

FARM COLONIES IN THE TREATMENT OF TUBERCULOSIS.

A DISCUSSION on this subject was opened at a meeting of the Tuberculosis Society on January 21st by Sir R. PHILIP. He stated that it was nearly twenty years since in the *BRITISH MEDICAL JOURNAL* (July 23rd, 1898), he had made a plea for the establishment of farm colonies for tuberculous patients. It was founded on the experience of the Royal Victoria Hospital, Edinburgh, which showed that in a considerable number of cases complete arrest of tuberculosis could not be attained within the ordinary time limit of sanatorium residence, nor even when it was considerably extended, and that work of a definite

purposive character, far from impeding cure assisted its completion. It was not easy to estimate the proportion of cases falling into the two groups: (1) patients discharged from the sanatorium in about six months fit to return to their ordinary occupation, and (2) those in whom return to the ordinary conditions of home environment and work was apt to lead to relapse. Sanatorium statistics, stated broadly, went to show that within four or five years some 50 per cent. of cases apparently arrested had relapsed even when care had been taken in the selection of patients for admission, and treatment had been regulated with the individual precision possible at such sanatoriums as Frimley or the Royal Victoria Hospital. He was appalled by what was occurring in relation to the more limited course of three months' sanatorium treatment now usually meted out to subjects of tuberculosis, all and sundry, under the Insurance Act. In his evidence before the Departmental Committee on Tuberculosis he had said that even when the period in the sanatorium was not curtailed, it would be desirable in from 20 to 25 per cent. of the cases to prolong the period of treatment, probation by residence in a colony. The farm colony was complementary to the sanatorium, affording a simple means, economically sound, for securing in a certain proportion of cases more permanent arrest of tuberculosis than, without undue expenditure, was possible at the sanatorium. The name "farm colony" had the attraction that it carried forward the open air idea, but it was not to be taken to imply limitation of the occupations open to the colonists.

Selection of Cases.—If a colony was to be of real practical value the cases admitted must be carefully selected; it must not be used as a dumping ground for all sorts of cases. Many cases of tuberculosis did not require residential treatment, but skilled surveillance at the home or the tuberculosis dispensary. The more advanced cases were segregated in the interests of themselves, their households, and the community; others, again, required close treatment at a sanatorium, either, in a certain number, until arrest had been attained or assured, or, in others, until the patient had mastered the principles of management and cure, provided always that the conditions to which he was to return were such as to admit of his putting the principles into execution. There remained patients whose lesions were of such a character as to require greater continuance of medical supervision and the prolonged maintenance of conditions and environment not attainable in their homes or work places. Arrest might be achieved by a longer stay at the sanatorium, but such prolonged residence at a highly equipped sanatorium was unnecessary and uneconomic.

Colony Life and Work.—The fact that the main object of a colony was to cure a patient of his tuberculosis seemed to have been lost sight of in some of the published statements with regard to colony schemes. Training must be subordinate to cure and adapted to achieve the ultimate purpose of a colony, which was the completion of the cure and the establishment of such relations to future work as would most tend to the maintenance of recovered health. For a certain number the only hopeful outlook after cure was to continue an outdoor life; with sufficient capacity and energy some would develop skill in some department of work which would ensure an ample livelihood later on. Included within the colony curriculum were such trades as carpentry, and the colony might embrace numerous departments provided the colonists were trained not only in the trade but in the daily application of sanatorium principles to their workshops and homes.

Results.—The work of the Royal Victoria Hospital Farm Colony, established in 1910, had been disturbed in various ways by the war, but it could be said that eighty-eight persons had been in residence, in almost every case for twelve months, and with very few exceptions discharged, with the disease arrested and with a first-rate working capacity. Dividing the records into those of colonists in whom bacteriological tests were positive and those in whom they were negative, the cases included as negative were those in which either tubercle bacilli were found on admission, or, in the absence of such proof (no sputum, etc.), a tuberculin test was decidedly positive. The returns as to after-history had been brought down to the autumn of 1917. The facts are summarized in the table.

ROYAL VICTORIA HOSPITAL FARM COLONY.

(Opened July, 1910.)

SUMMARY OF SUBSEQUENT HISTORY OF ALL "COLONISTS" DISCHARGED UP TO OCTOBER, 1914.

(The facts, in most cases, brought up to date (August, 1917), and in the remainder up to December, 1916.)

I. "Colonists" in whom Bacteriological Tests were Positive.

Date of Discharge.	Total No.	Traced	Alive in Good Condition.		Alive in Indifferent Condition.		Dead through Natural Causes.	
			No.	Per cent.	No.	Per cent.	No.	Per cent.
(a) Oct., 1911 ...	13	8	5	62.5	1	12.5	2	25.0
(b) Oct., 1912 ...	31	25	15	60.0	1	4.0	9	36.0
(c) Oct., 1914 ...	81	68	41	60.3	4	5.9	23	33.3

II. "Colonists" in whom Bacteriological Tests were Negative.

Date of Discharge.	Total No.	Traced	Alive in Good Condition.		Alive in Indifferent Condition.		Dead through Natural Causes.	
			No.	Per cent.	No.	Per cent.	No.	Per cent.
(a) Oct., 1911 ...		1	0	—	0	—	1	100.0
(b) Oct., 1912 ...	3	2	1	50.0	0	—	1	50.0
(c) Oct., 1914 ...	7	5	3	60.0	0	—	2	40.0

In appraising the value of results it must be kept in view that all were cases in which treatment at the sanatorium for periods often exceeding six months had failed to secure decisive results; they were typically those which would have gone to swell the roll of sanatorium failures.

Finance.—Life at the colony should be much less costly than at an ordinary sanatorium; everything was simple, the bed and board good, but nothing extravagant. A considerable part of the food might be found on the spot as the result of the colonists' own activity, and if, as was the ideal arrangement, the colony was linked with other tuberculosis institutions and perhaps other hospitals in the neighbourhood, a considerable amount of co-operation might be effected. Waste material from the sanatorium or hospital might be used in the colony piggery and poultry yard, while potatoes were supplied by the colony to the other institutions. The Royal Victoria Hospital Farm Colony had to begin by adapting an old mansion house and getting its parks into cultivation. For the first few years the debit balance was large, but by 1915-16 it had been reduced by over 50 per cent. The war had stopped development, prevented increase in the number of colonists, and added greatly to the cost of food and supplies of all kinds; otherwise the financial results would have been better. Still, the figures for 1916-17, after three years of war, showed that the actual cost, after deducting revenue from total expenditure, free of rent, was £1 2s. 5d. a week for each colonist. Each case in the colony must be subject to individual care. In the early days after the admission of the patient the medical superintendent must gauge the degree and kind of arrest possible and the form of activity most likely to conduce to recovery and maintain it. The medical superintendent must not only understand tuberculosis, but have some knowledge of farming and industrial work, and must distribute jobs and adjust training in the interests of the colonists individually, as well as in the common interest. Too much had been made of the disadvantage of an enforced change of occupation; it was not always necessary; and by the interposition of a year of the simple outdoor active life of the colony a colonist might be restored to health and physiologically trained, and then frequently resume his old work with considerable confidence. Experience, however, proved that where a change of occupation was desirable it was achieved with less difficulty than might be expected. Clerks, miners, bakers, tailors, and ironmongers had become farmers; shopmen had become travellers and van-drivers, clerks railwaymen, and saddlers carters. Brief reference was made to the question whether beyond the provision of institutional treatment more was to be done for the tuberculosis patient in the way of subvention when under control or if he continued disabled, but it was considered too large a subject for discussion at the time. In conclusion, Sir Robert Philip said that if the treatment

of tuberculosis was to be really effective it must be freed from the hampering influence of the *res angusta domi*, and pointed to the arrangements made by the Ministry of Pensions in relation to institutional treatment of discharged sailors and soldiers as a precedent.

Discussion.

Dr. NOEL BARDSWELL considered that the principle of farm colonies was sound, for by them treatment was prolonged and suitable accommodation provided. There was great difficulty in the employment of consumptive labour except in colonies or in sanatoriums.

Dr. A. H. MACPHERSON (resident physician-superintendent, Hairmyres Colony, Lanark) said that the farm colony must be based on sound economic lines, and at the same time so treat and train a patient that he became capable of earning a livelihood under suitable conditions with the risk of relapse reduced to a minimum. Patients with the disease dormant and who no longer required nursing were transferred to the farm colony, thus relieving pressure on the sanatorium. Each department should be a separate unit, complete with equipment in every detail for carrying on the work assigned to it. The work of the farm colony must be as varied and interesting as possible in order to supply different grades of labour and at the same time sustain interest. A farm colony should be situated within a reasonable distance of a good market, and should not be contiguous to the sanatorium with which it worked in co-operation. The residences for colonists need not be elaborate. Buildings for the rearing and housing of stock should be well designed, kept scrupulously clean, and ventilation should be a special feature. Whatever stock was kept should be typical of the breed. Every colony should have a minimum staff, consisting of a physician-superintendent, a nurse-matron, and a farm grieve or bailiff. The outdoor staff should be engaged by and under the direct control of the physician-superintendent. The appointment of the matron should be approved by him also. There were two farm colonies in existence in Scotland—the Royal Victoria Hospital Farm Colony, inaugurated in 1910, and the Hairmyres Colony in Lanarkshire of later date. Both worked in intimate co-operation with associated sanatoriums. The usual period of residence was about one year. The Hairmyres Colony was on a large scale and held in it all the elements of success. A pavilion for children suffering from tuberculosis was opened in 1914, and a certificated teacher was in residence, who took care of the patients during school hours and when working in the garden or forestry. The farm colony was destined to form an economic factor of high value in the treatment and training of children with tuberculosis. They were hardened to resisting point and, on discharge, were in a condition to cope with unfavourable environment. It had been proved that risk of infection to stock and produce might be entirely disregarded on a colony under strict medical supervision.

Dr. F. N. K. MENZIES said that conclusions had been reached on insufficient grounds that sanatorium treatment was a failure. Proper perspective was lacking as to the type of clinical case suitable. Certain aspects of farming were appropriate, such as market gardening and the small holding type. A comprehensive scheme was necessary for large areas such as London.

Dr. JOHN SORLEY said that rigid selection of cases was necessary for sanatoriums and farm colonies. The crux of the matter lay in the treatment of tuberculosis of infants and children, because they showed the greatest tendency towards regaining a power of resistance.

Drs. JANE WALKER and ESTHER CARLING took exception to the name "farm colony" on the ground that few patients leaving a sanatorium could do farm work. Dr. F. R. WALTERS suggested the name "health colony." Those suitable for admission were (1) slight cases, and (2) severe and more chronic cases. Those suffering slightly were not conscious of a bad breakdown and did not like sanatoriums. He suggested a short period of training in a sanatorium after which they might be induced to go to a health colony.

THE French Government has drafted a bill to render illegal the use of casein for any other purpose than human consumption.

Reviews.

ACUTE POLIOMYELITIS.

DR. DRAPER'S compact account of the disease in his book entitled *Acute Poliomyelitis*,¹ contains his experience at the Hospital of the Rockefeller Institute for Medical Research, New York, and may be said to reflect Flexner's teaching at that institute both before and after the great epidemic of 1916. His object is to present the most recent conception of this general infective disease, in the course of which paralysis is but an accidental occurrence; there are thus two distinct phases of the disease—one of general systemic infection, the other characterized by a disorder of the nervous system. The author is rather cautious about Flexner and Noguchi's globoid bodies; he states that their presence has been confirmed by several laboratories, that there has been no complete disproof of their specificity, and that whether or not they are the same biological entity as the polymorphic organism with affinities to the streptococcus described by Rosenow and others, must be left for future research to decide. In acute poliomyelitis widespread visceral changes are mentioned, especially in the lymphatic organs which show hyperplasia.

Three types of the clinical picture may be recognized: in the first group the patient appears to recover completely or in part from the general systemic infection, and then to suffer an attack on the cerebro-spinal tract; there are thus two periods of symptoms, or humps, with an interval of well-being, and hence this is termed the "dromedary" type; in the second or "straggling" type there is no interval of freedom from symptoms; and in the third or sudden onset type implication of the nervous system is obvious from the first, but is really preceded by an unobserved because mild systemic stage. From 50 to 80 per cent. of the cases attacked do not suffer any implication of the nervous system, and these cases, formerly spoken of as abortive, are far commoner than has been realized in the past. The meninges have escaped invasion, and the cerebro-spinal fluid is normal, so that the case ends with the first hump of the dromedary type. In the early stage of meningeal implication the cerebro-spinal fluid is rarely opalescent or turbid, but contains multilobed cells, resembling and usually called polynuclears, though probably wandering tissue-cells, which rapidly give place to lymphocytes, so that in twenty-four to thirty-six hours 90 per cent. of the cells are lymphocytes. With very few exceptions this cell count runs parallel with the intensity of the "spine sign," namely, pain and rigidity on flexing the neck forwards. That this spine sign may precede changes in the cerebro-spinal fluid is explained as due to pressure on the ganglia on the posterior roots, which experimentally may be seen to be invaded before the meninges, during flexion of the neck. Combined intrathecal and subcutaneous or intravenous injection of serum from a recovered patient should be begun early, within thirty hours of the onset of meningeal invasion. This book gives a clear account of the subject, and well carries out the author's intentions.

THE FUTURE OF THE DISABLED SOLDIER.

THE problem of the future employment of mutilated soldiers is acute in this country, but if the statement that the total number of our casualties is less than that of the French dead be even approximately true, the dimensions of the question with which our allies have to deal is apparent. In his little book on the *Future of the Disabled Soldier*,² Dr. HUTT deals at some length with the experience of France and Belgium in dealing with this problem.

Both those countries had the advantage of possessing special institutions for the training of workmen mutilated in peace time, which supplied experience and data for the development of much more extensive organizations. L'Institut Militaire Belge de Rééducation Professionnelle at Port Villez, of which we gave an account some time ago, is now, Dr. Hutt says, "not only self-supporting, but has long

¹ *Acute Poliomyelitis*. By George Draper, M.D. With a foreword by Simon Flexner, M.D. London: William Heinemann (Medical Books), Ltd. 1917. (Pp. 149; 19 illustrations. Price 7s. 6d.)

² *The Future of the Disabled Soldier*. By C. W. Hutt, M.A., M.D. Cantab., D.P.H. Oxford, Temporary Lieutenant R.A.M.C. London: J. Bale, Sons, and Danielsson, Limited, and T. Fisher Unwin, Limited. 1917. (Cr. 8vo, pp. x + 199; 14 figures. 6s. net.)

ago paid back the Belgian Government the entire capital cost of installation." It makes and supplies to the Belgian army a large number of tools and other useful articles, and teaches forty-three different trades. A good deal of the economy of this institution rests upon the fact that all Belgians are mobilized, and teachers and others only receive army pay.

In France there is a large number of *écoles professionnelles* busily at work which combine the functions of curative workshops with those of training establishments. In these, as in the Belgian schools, the re-education of the left hand is specially attended to. In connexion with the training of the wounded the scientific work of Dr. Jules Amar is worthy of notice. In 1912 he was appointed Professor of the Physiology of Work at the Paris Conservatoire des Arts et Métiers, and he has since applied his methods of investigation and record to the study of the work of disabled soldiers. Dr. Hutt reproduces illustrations showing the apparatus used registering movements and energy produced in the use of various tools. These methods not only furnish valuable information as to the effort made in using tools, but also show the onset of fatigue, and enable the observer to check over-exertion and watch the progress made. Dr. Amar's table showing the average power of stumps of different lengths is of great interest. Taking the power of the whole segment of the limit as 100, the power of a stump of half that length is generally about 65, except in the case of the leg below the knee, where it is 73. Dr. Amar estimates that 80 per cent. of the amputated will repay re-education.

Dr. Hutt gives succinct accounts of the work being done in Germany, Canada, Australia, and New Zealand, and also of the curative workshops advocated and established under Sir Robert Jones, and at Queen Mary's hospitals at Roehampton and at Brighton, and the Polytechnic in London. These curative workshops will play an important part in the orthopaedic treatment of wounded and of discharged men for some time to come. Many men who have lost a leg are now earning far better wages than they were getting before the war, not because of the rise in rates of pay, but because they have become skilled instead of unskilled workers. The loss of an arm is a more serious handicap but one which training and perseverance often nullifies. Every person who is interested in the reinstatement of the wounded in the ranks of industry will find Dr. Hutt's book instructive and useful. Especially is a knowledge of what is being done in other countries stimulating and destructive of undue self-complacency.

NOTES ON BOOKS.

SIR FRANCIS DARWIN has published a charming book of essays, *Rustic Sounds and Other Studies in Literature and Natural History*.³ The first paper gives its title to the book: in it the author recalls the rustic sounds of his boyhood's home at Down—the primitive notes of birds, trees, and running water, the swish of scythes, and the voices of haymakers. This love of the countryside is revealed also in a story of a lane in the Cotswolds. Biographical essays deal with his kinsmen, Francis Galton and George Darwin, and with Stephen Hales, who in the eighteenth century was a pioneer in vegetable as well as in animal physiology. The author leads us again to his own subject in the chapters on the movements of plants and on picturesque experiments in botany. His feeling for the poetry of research is revealed in many pages. "After all," he says in a genial outburst, "the real fun of science begins when one finds out something that was not known before." There are three papers on the aims and methods of education which are especially interesting at the present time. It is to be noted that Sir Francis Darwin has a very poor opinion of the classics as a training for the average boy, and protests strongly against the "great Moloch" of examination. As was to be expected from the subjects he selects to treat in this book, Sir Francis Darwin is an Austenian, but we wonder whether his admiration of the divine Jane does not carry him too far when he suggests that she is the most re-read author of the last hundred years. Music also furnishes him with a theme; there is an erudite little essay on the pipe and tabor, the traditional instruments for English folk dancing, and an inspiring fragment on war music—both originally delivered as addresses to a society of Morris dancers.

³ *Rustic Sounds and Other Studies in Literature and Natural History*. By Sir Francis Darwin, F.R.S. London: J. Murray. 1917. Cr. 8vo, pp. 231; 8 figures. 6s.)

Lastly, there is a very sympathetic paper on dogs and dog lovers, with its reluctant admission that, after all, it may be that not to care for dogs is no more a blemish than a lack of musical ear.

Messrs. Longmans have published in a well printed, well illustrated pamphlet (price 3d.) entitled *The Trail of the Barbarians*, a translation by Mr. Ford Madox Hueffer of the small book written by Pierre Loti for French school children. It relates a journey he made through the devastated districts, describing the ruined towns, the desecrated churches, the smashed farm implements, and the hacked fruit trees. Revised into good idiomatic English, the pamphlet would be a more valuable piece of propaganda literature than most of its forerunners.

MEDICINAL AND DIETETIC PREPARATIONS.

Jardox.

WE have received from Messrs. Jardox, Ltd., Crystal Palace Works, Anerley, a sample jar of Jardox, which is claimed by the makers to be a pure beef food containing the albumin and fibrin of the meat in an easily digested form, in addition to the usual extractives present in preparations of this type. Our analysis shows it to contain:

Moisture	40.7 per cent.
Total nitrogen	6.87 "
Mineral matter	14.1 "

When mixed with boiling water in the proportion directed the resulting liquid is very palatable, and bears quite a close resemblance to home-made beef-tea prepared in the usual manner.

VITAL STATISTICS IN ENGLAND AND WALES, 1917.

WE are indebted to the Registrar-General for the following statement showing the birth-rates and death-rates and the rate of infantile mortality in England and Wales and in certain parts of the country during 1917.

ENGLAND AND WALES.

Birth-rate, Death-rate, and Infant Mortality during the Year 1917 (Provisional Figures).

	Birth-rate per 1,000 Total Population.	Civilian Death-rate per 1,000 Civilian Population.	Deaths Under One Year per 1,000 Births.
England and Wales	17.7	14.4	97
95 great towns, including London (populations ex- ceeding 50,000 at the Census of 1911)	18.0	14.6	104
148 smaller towns (popula- tions from 20,000 to 50,000 at the Census of 1911)	17.9	13.1	93
London	17.4	15.0	103

The following table, which we have compiled from the statements published for ten years, will be of interest. The figures (not standardized) of the death-rates do not disclose any very distinct movement; the deaths of infants appear to indicate a slight increase. The most disquieting set of figures are those showing a further marked decline in the birth-rate since 1914.

ENGLAND AND WALES.

	Births per 1,000 Total Population.	Deaths per 1,000.	Deaths Under One Year per 1,000 Births.

British Medical Journal.

SATURDAY, FEBRUARY 2ND, 1918.

THE ARMY MEDICAL SERVICE TO-DAY.

GENERAL SIR A. HUNTER-WESTON, who commanded the famous 29th Division at the landing at the Dardanelles, in a maiden speech in the House of Commons on January 24th, when discussing some of the criticisms which army administration has had to encounter, said: "Objection has furthermore been made that sufficient use has not been made of the best brains, and that there is a prejudice against the Territorials and the new army men. Nothing could be further from the truth. When men are fighting for their lives and honour, as we are now, they ask, not who a man was, not whether he was a Regular, a Territorial, or a New Army man in the past; they ask what is the best man now? We want to get the best assistance to help us to win the war, and a man at the front is taken for what he is, and not for what he was." Lord Derby repeated this assurance on January 29th and gave some statistics of the number of regular, reserve, special reserve, new army, Territorial Force, and overseas officers holding general and administrative staff appointments. It appears that the number of regulars so employed is 1,944, of the reserve and special reserve 352, and of the new army, Territorial Force, and overseas officers 1,022. The report of the Committee appointed over a year ago with Mr. Winston Churchill as chairman, but which has concluded its labours under the chairmanship of Colonel Lord Burnham, recommends in its second report, issued this week, that "the selection of officers for administrative medical positions should continue to be made from the Royal Army Medical Corps as a whole" (see p. 164).

It is satisfactory to know from an officer so distinguished and experienced as General Hunter-Weston that the leaders of the combatant forces take the view he expressed, and it is natural for medical men to ask if there is the same freedom from prejudice and the same readiness to make full use of the best brains, wherever found, in the administration of the Army Medical Service. If any change of attitude has occurred, it must be of recent origin, and there is still a widespread belief that "thus far and no further" expresses the attitude of the chief regular medical officers towards their Territorial or temporary brothers.

It seems well, therefore, to consider this matter, not in any carping spirit, nor with any thought of ousting the capable Regular from appointments to which his life's service fits and entitles him, but in the hope of contributing something towards the solution of the problem of how to make the best use possible of every medical officer in the army, whether Regular, Territorial, or temporarily commissioned. We propose to examine into the origin of the criticisms to which we have referred, the grounds on which they are justified, and the methods available to remove the causes of any complaint which can be shown to be legitimate and well founded. In the early days of the war, before the first burst of enthusiasm had subsided into the recognition of war conditions as part of our daily life, men were content to accept the organization which had been built up by the expert corps of the old army, and placed themselves voluntarily and

without question under the system. The number of regular medical officers of the R.A.M.C. was originally a little over 1,000, but during the first six months the number was raised to about 1,200, chiefly by the employment of retired officers. While the new armies were being formed and trained at home and the force abroad was relatively small, a sufficient proportion of capable administrators could be found among the regular medical officers on the active list to cope with the situation. The officers of the Special Reserve, R.A.M.C., had been at once called up when war broke out, and medical officers of the Territorial Force were of course mobilized as a part of that force. At an early date also a considerable number of civilian medical men received temporary commissions; they numbered, we believe, nearly twelve hundred before the end of 1914. Since then this number has been increased tenfold as the new armies grew and the area of operations extended, until at the present time the civilian element outnumbers the regular military probably by twelve to one; the total number of medical officers in the army, indeed, equals, if it does not exceed, the number of general practitioners left to deal with the whole of the civil population of England and Wales.

The civilian addition to the medical officer personnel of the R.A.M.C. included men engaged in every variety of medical practice, and among them men of wide experience and the highest capacity in clinical medicine and surgery. It is due to the heads of the Army Medical Service to say that they at once recognized the value of these recruits on the professional side, and made very full use of their capacity in such parts of the duties of the service as directly concern the treatment of the sick and wounded. They availed themselves also of civilian experience in matters of sanitation, and many modifications in the details of administration were introduced into this most important part of military organization. The use of consultants in every branch of medical science has been of enormous value. That the treatment of the sick and wounded in the present war surpasses anything achieved previously is in largest measure due to this recognition of the value of civilian assistance on the professional side.

We are now well on in the fourth year of war, and the civilian practitioners who entered the Royal Army Medical Corps in the earlier years have learnt much of army organization and army methods, and have had time and opportunity to view the situation in the light of their experience in the field. It is inevitable that they should have compared the work they are doing in the army with the work they used to do in civil life. Long hours of leisure have given to some the time to clarify their views on the administration of an Army Medical Service. They seem to have found it difficult to obtain consideration of these views by administrative regular officers, whose minds perhaps are occupied by more immediately urgent matters. Temporary officers have found themselves in unsuitable or uncongenial posts, and they wonder who is responsible for the selection, and on what evidence it was made. Again, surgeons busy in the practice of their art in the days before the war are apt to criticize the continued enforcement of old army regulations requiring them to prepare documents in triplicate in their own handwriting when it seems to them conceivable that the copying would be done as well by a typist from the W.A.A.C. They know that the supply of doctors for the civil population of these islands has been depleted until it is certain that no more can be secured without causing serious difficulty to the community.

It is not surprising, therefore, that medical officers have asked themselves whether the authorities of the Army Medical Department are fully alive to the necessities of the future. Many have come to the conclusion that the department's arrangements ought to be improved in two directions. They consider that it is extravagant in its use of medical officers, and that it is reluctant to admit defects in its methods of administration. These critics think that improvement in the administration of the Army Medical Department would accrue from greater infusion of civilian capacity on the administrative side.

Thus in the Army Medical Service, as now constituted, a mass of personal grievances has arisen, based largely on the charge of extravagance in the use of medical officers, as regards the time occupied in their duties, the way in which their talent is made use of, and the numbers employed. It is, of course, easy to assert that men love a grievance, or to recall the statement that no army ever had so many grievances as Wellington's. Nevertheless, when grievances are so widespread that almost any man will unburden himself privately on the matter, and when opinion on the cause of grievances is so concordant, it would seem wise on the part of those in charge of the machine to consider whether some adjustment of its parts may not be desirable.

The examination of the question whether the complaint is justified is a lengthy matter, and cannot be fully developed in this article. But we may at least put together some of the questions which appear to call for investigation. We hope that their formulation may be of assistance, especially to the Army Medical Department, but also perhaps to the Ministry of National Service, for both are concerned with the very difficult problems which have arisen.

The questions that seem to require close consideration are, in the first place, whether in fact a sharp line is drawn between administrative and professional work, and if so whether this sharp line should be maintained. Another question is whether it is not the case that larger emoluments attach to administrative posts than to those concerned with professional work, and, if this be so, whether a regular officer R.A.M.C. who has reached a certain rank may not in consequence be diverted from the professional work in which he is really interested to administrative work for which he may have no special capacity or experience? The next question which arises is whether officers of the Territorial Force or those holding temporary commissions are being appointed to administrative posts. An order encouraging action in this direction was issued last summer; how far it has been acted on we do not know nor to what kind of post such officers have been appointed. Again, what is the official position of the consulting physicians and surgeons with regard to an expression of their views on administrative questions? Finally, it has to be asked whether the office and clerical methods of the Army Medical Service are up to date, whether the system required to be followed in furnishing reports could not be simplified, and whether the methods of filing documents for reference and preparing card indexes, as well as other parts of the machinery used in a large business, have been adopted in the Army Medical Service.

The justification of the complaints which are made depends largely upon the answers to these questions. From the evidence at our disposal we gather that there is no doubt that some at least of the older regular medical officers draw a very decided line between administrative and professional work. Officers holding such appointments as those of D.G., D.M.S.,

and D.D.M.S., and members of their staffs as a rule do no professional work, nor is it wise in most cases that they should interfere in work to which many of them have become unaccustomed. On the other hand, it does not appear that these directors are commonly in very close touch with the medical officers under their command, nor that they have any thorough knowledge of the capacities of these officers. It would appear that their acquaintance with the varying capacities and experience in practice of medical officers serving under their command is often picked up in a rather casual way, as though it were assumed that every medical officer is capable, as Wellington said of his Peninsular army, of "going anywhere and doing anything." Consultants, drawn from civil life, are attached to the armies, and are no doubt prepared to advise on the capabilities of medical officers when the matter is brought to their notice, but we cannot gather that this is done systematically from front to base, nor do the consultants appear to occupy any official position in the deliberations at various head quarters. With an army in which the civilian-derived element now preponderates to the extent of twelve to one, it would seem advisable to make far more official use of the consultants than appears to be the rule.

If it should be proved that there are grounds for the complaint that the Army Medical Department does not make full use of the best brains of the medical profession, and if it be found that it is on the administrative and organizing side that the fault lies, what remedy or remedies should be applied? To us it seems that there are two directions in which improvement should be obtainable. First let the Army Medical Department invite the assistance of capable non-regulars in every capacity in which they can be useful. Let it establish officers' branches in connexion with the department at home and the various general head quarters, and give the staff of these branches every facility for gaining knowledge of the capabilities of the medical officers working at each front. Every source of information should be at the disposal of these officers' branches, and the senior officer of such a branch should be present at, and take part officially in, such administrative discussions at head quarters as concern the use and distribution of personnel. Secondly, let the Army Medical Department overhaul its office machinery, and consider whether its work could not, with advantage to economy of personnel and speed of working, be reorganized on more modern business lines.

THE EFFECTS OF EXPERIMENTAL HYPERTHYROIDISM.

THE relation of disturbances of the ductless glands to conditions arising during the war has attracted a certain amount of attention. At a comparatively early stage the view that the soldier's heart or "effort syndrome," the name suggested by Dr. T. Lewis, was due to hyperthyroidism came forward and was sufficiently debated. As the most obvious manifestation of a general over-stimulation of the ductless glands by excitement or the toxæmia of infections is hyperthyroidism, this is often regarded as the sole change, but Dr. A. F. Hurst pointed out that in reality the disorder is more complex, and concerns all the endocrine glands. The importance of the inter-relations of these glands has long been recognized, especially in connexion with the pathogeny of diabetes, and it has been thought that between thyroid and pancreas and between pancreas and chromaffin tissue there is

a mutual restraining influence, and between thyroid and chromatin tissue a mutually stimulating influence. In these difficult problems imagination and speculation, valuable as they undoubtedly are in their way, must be controlled by exact experimental researches, such as those recently published by Professor P. T. Herring.¹

In his first paper he records the results of careful investigations of the influence of thyroid feeding, and of the weight and adrenalin content of the adrenals. Male white rats were given daily for about twenty-five days 0.2 to 0.5 gram of fresh ox thyroid, with the result that the medulla, and more especially the cortex of the adrenals, were found to have undergone hypertrophy, and that the adrenalin content was increased absolutely, though diminished relatively, to the percentage weight of the glands. A further research on the action of thyroid upon the growth of the body and organs of the white rat, while confirming in the main the results obtained by E. R. Hoskins, brings out some new points. Rats of both sexes, the females being found to be more susceptible, were given 0.1 to 0.2 gram of fresh ox thyroid in their food daily and weighed weekly. When the experiment was finished the organs were weighed and examined but the full histological details have not yet been published. Thyroid feeding causes profound changes in the body, eventually leads to death, and "acts on metabolism as a forced draught acts on the fuel in a furnace." As estimated by body length, the growth of young rats is little affected but the body weight is, on the whole, diminished, though the loss due to disappearance of fat may for a time be counterbalanced or even more than counterbalanced by the increased weight of many of the viscera. In addition to the adrenals the heart, kidneys, and pancreas are constantly and greatly hypertrophied; the weight of the heart being more than trebled, that of the adrenals and pancreas more than doubled. The hypertrophy of the kidneys is closely related with that of the heart; both correspond to the amount of thyroid consumed, and are prominent features in rats dying suddenly, as sometimes occurs, while thus rendered hyperthyroidic. The liver, spleen, testes, and ovaries are also, though not so markedly, enlarged. The hypertrophy of all the organs mentioned was explained by Hoskins as due to increased metabolism, and Professor Herring accepts this view as regards the liver, spleen, testes, and ovaries, but considers that the extreme enlargement of the adrenals, heart, kidneys, and pancreas points to the existence of some additional factor. Thus, there is an increased production of adrenalin in thyroid-fed animals, and the maintenance of their health appears to depend on this; further, in Graves's disease, in which there is usually believed to be excessive thyroid secretion, an increased amount of adrenalin has been found in the blood, and its medicinal use is sometimes followed by temporary improvement of the cardio-vascular symptoms; these considerations suggest the conclusion that the increased output of adrenalin is compensatory and overcomes the effects of thyroid in the circulation. These additional factors in combination with heightened metabolism may be responsible for the great hypertrophy of the heart and kidneys. The pancreatic enlargement may be connected with regulation of carbohydrate metabolism which would otherwise be upset by the excessive amount of adrenalin, but it should be noted that islands of Langerhans were not proved to be more numerous than in normal conditions. In young rats the growth of the uterus and of

the pituitary body appears to be inhibited by thyroid feeding, and a close correlation between these organs is suggested.

As the weight of the thyroid is reduced, and its cells histologically thinned and flattened, it is reasonable to assume that experimental hyperthyroidism checks the functional activity of the gland. It is interesting in this connexion to find that thyroid feeding has not any constant effect on the thymus, whereas this gland is practically always persistent and large in Graves's disease, in which the hyperthyroidism or dysthyroidism is intrinsic, and thus contrasts with its extrinsic production in this research.

THIS WEEK'S ISSUE.

It has been necessary considerably to curtail the number of pages in this issue owing to serious damage by fire to the machines on which the JOURNAL is printed. It has indeed been possible to publish a number this week at all only through the help generously offered by other printers, for which courtesy we desire to express our gratitude. We must ask correspondents whose communications have been omitted to accept this explanation.

LORD RHONDDA ON NATIONAL RATIONING.

LORD RHONDDA's speech at the Mansion House on January 24th was naturally of great interest, but the details of his rationing scheme were not sufficiently developed for extended comment to be helpful; we shall merely notice a few points which require to be elucidated. Lord Rhondda is reported to have said that the distribution clearing house which he is setting up "will show how much meat, bacon, margarine, and butter should go into different districts, making allowance for districts in which heavy work is being carried on." This may only mean that an effort will be made to secure priority of distribution to such districts, but if, as the actual wording seems to imply, manual workers are to be allotted larger rations, something more than a clearing house is needed, and the individual allocation of supplies ought not to be left to local control committees without further instructions. We think that a common practice of butchers at present is undesirable. The practice in question is this. The butchers cannot secure more than 50 per cent. of their October supplies, and they ration their regular customers uniformly on this basis. But, as the wealthier customers consumed proportionally far more meat than the working classes, a 50 per cent. reduction of supplies to the latter is a much greater hardship than in the case of the former. This is a grievance which should be dealt with at once. Another point is as to the position of the army. The public will certainly endorse Lord Rhondda's contention that the army must come first in supplies, but it may well prove possible to reduce the meat rations supplied to soldiers employed on clerical and other light work, especially at home. It is, indeed, very disputable whether the proportion of energy provided in the form of animal food should be maintained at its present level amongst the troops in training at home. It is extremely difficult to overcome the popular prejudice in favour of meat, a difficulty which, as we have so often pointed out, the injudicious and ill-informed advertising campaign of the Food Ministry last spring has notably increased. It is not easy to maintain on physiological grounds that the men in training or on home defence ought to receive a larger meat ration than manual workers in essential industries. We are, however, sensible of the fact that changes in an army ration can only be made with caution. We do not doubt that Colonel Weigall, M.P., who has been appointed by Lord Rhondda to deal with questions of rationing in the public services, will carefully consider the point. As we go to press an apparently inspired paragraph

¹ P. T. Herring: *Quart. Journ. Exper. Physiol.*, London, 1917, xi, pp. 47-57, 231-253.

In a daily newspaper asserts that the Army Council is about to modify the army ration with a view of meeting the objections just noted.

WAR BREAD.

In the second of the series of lectures at University College, London, on biological problems of the day, delivered on January 28th, Professor F. G. Hopkins, F.R.S., said that, with the goodwill of miller and baker, the nation might benefit rather than otherwise from the consumption of the war bread. The prejudice in favour of the pure wheat loaf was very ancient, as a poem by William Langland, written in the fourteenth century, bore witness, but such prejudice had little support from the strict point of view of nutrition. The choice of wheat as against other cereals was not due to any pre-eminent superiority in nutritive value, but to the secondary consideration that it was wheat alone which furnished (according to its strength) the spongy texture of the loaf which, especially during the last generation, had come so greatly into demand. Wheat used as an exclusive food for animals stopped their growth or their reproductive capacity. The drawback of wheat, apart from the rather unsatisfactory adjustment of its protein, was the small proportion—1 per cent.—of fat in its constituents; hence the logic of bread and butter. No cereals were satisfactory sources of fat, but both oats and maize were distinctly better than wheat in this respect; if the cereals were mixed the result was a better loaf. A loaf which contained more than one cereal, therefore, should not be looked upon as adulterated. Another change in the loaf which the public had had to face was the inclusion of more of the wheat grain. Professor Hopkins described some experiments carried out lately by a committee of the Royal Society with a view to determining the digestibility of war bread in certain carefully dieted individuals. In the case of the original war bread, in which 80 per cent. of the grain was used, the average amount digested was 96.1 per cent., and the range of variation among the twelve individuals who were the subjects of the experiment was very slight; the highest was 97.1 per cent., and the lowest 95.1 per cent. In the case of the present war bread of 90 per cent. extraction the individual variation was just as slight, and the average digestibility was 94.5 per cent. Thus, even allowing for the diminished digestibility in the latter case and for the diversion of the offal from the foodstuffs previously available for animals, it was a sound national economy to use the 90 per cent. flour instead of the 80 per cent.; the gain was equivalent to one-twelfth of the whole supply, and the advantage over the pre-war 70 per cent. was, of course, correspondingly greater. The additional vitamins obtained by reason of the retention of the husk and embryo of the grain was another argument in favour of war bread, especially when bread bulked largely in the dietary, with the consequent difficulty of getting sufficient vitamins from other sources. The occasional "ropiness" of the bread was only to a small extent due to the extra percentage of wheat; much more important was the subsequent treatment of the loaf, and experience in this respect was diminishing the likelihood of the disease.

THE ANAEROBIC BACTERIA OF WAR WOUNDS.

ALTHOUGH there was a large pre-war literature on anaerobic bacteria, the subject was never really dealt with according to the more modern exact bacteriological technique; and as a result of the difficulty of obtaining pure cultures of these organisms any particular anaerobe cannot be identified with the same degree of certainty as in the case of an aerobic. The frequency of gas gangrene during the war has greatly increased the output of this work, and Major Carroll G. Bull, U.S.M.C., has already produced an anti-toxic serum against infections with *Bacillus welchii*.¹ In a

recent publication of the Medical Research Committee Dr. James McIntosh² has published the results of an elaborate investigation of the anaerobic organisms and cleared away some of the obstacles to more accurate knowledge on the subject. The employment of a new apparatus for the isolation and cultivation of anaerobic organisms, designed in conjunction with Dr. Paul Fildes (now honorary Staff Surgeon R.N.V.R.), with whom the earlier part of the work was carried out, enabled pure cultures to be obtained. Two hundred individual strains have been isolated and examined. With the exception of the *B. welchii* group, for which agglutinins are not produced, the identification of a strain can be much simplified by the use of agglutinating serums prepared from rabbits. Although agglutinins could not be demonstrated in serums prepared against members of the *B. welchii* group, the presence of specific antibodies in these serums was shown by means of the complement fixation test. Out of nineteen different types of anaerobes identified by Dr. McIntosh all except *B. chauvoei* and *B. botulinus* have been obtained from war wounds. A detailed description of these nineteen types, illustrated by fourteen plates, is given. Only two of these anaerobes were found to be truly toxogenic—a result opposed to Bull's and Pritchett's description of an exotoxin for *B. welchii* (vide BRITISH MEDICAL JOURNAL, 1917, ii, 432). The anaerobic flora of wounds is shown to be much more complex than some of the earlier publications during the war indicated, and in the majority of gangrenous wounds, both acute and chronic, several anaerobes can be isolated; of the pathogenic varieties the most frequently isolated are the *B. welchii* group, and next in order of frequency Pasteur's "*Vibrio septique*," which must now be regarded as the same organism as Koch's bacillus, afterwards described under the name of malignant oedema; while of the non-pathogenic varieties certain forms of *B. welchii* and *B. sporogenes*, which has often been mistaken for the bacillus of malignant oedema, are almost constant. Gas gangrene may therefore be regarded as a clinical symptom-group which can be produced by one or more of a series of anaerobic bacteria. A further memoir on the important practical questions associated with the pathology of gas gangrene is now in preparation.

ACUTE POLIOMYELITIS IN A CARRIER.

FLEXNER's view that acute poliomyelitis is spread by personal contact, though based on clinical observation and experiment, is not universally accepted, and as alternatives some form of insect transmission or an unknown mechanism have been suggested. Taylor and Amoss³ support Flexner's contention by the record of poliomyelitis in a family of four children living in a village otherwise free from the disease. The eldest boy was exposed to infection when away from home, and ten days later, after his return to his family, developed the disease and subsequently died. Four days after he became ill nasopharyngeal irrigations taken from his sister and one brother were injected intracerebrally into monkeys, which subsequently became paralytic. The nasopharyngeal irrigations therefore contained the virus, and the sister and the brother were thus shown to be carriers. As the brother had a febrile attack just before the irrigation, it is probable that he had a non-paralytic or abortive poliomyelitis. The other brother, aged 7 years, who could not be irrigated, developed the disease two days later. The sister became ill with acute poliomyelitis five days after she was shown to be a carrier. This is the first instance in which a proved carrier has

² *The Classification and Study of the Anaerobic Bacteria of War Wounds*. By James McIntosh, M.D., associated at the beginning of the work with Paul Fildes, M.B., B.C., Honorary Staff Surgeon R.N.V.R. With Supplement on Methods for Cultivating Anaerobic Bacteria, by P. Fildes, M.B., B.C., National Health Insurance, Medical Research Committee, Special Report Series No. 12. London: Sir Joseph Causton and Sons. 1917. (Pp. 74; 15 plates.)

³ E. Taylor and H. L. Amoss, *Journ. Exper. Med.*, Baltimore, 1917, xxvi, 745-754.

¹ BRITISH MEDICAL JOURNAL, 1918, i, 62.

been known to develop the disease. The author's suggestion that every case of acute poliomyelitis has been a carrier is logical, but does not obtain any support from the analogy of cerebro-spinal fever. Among the large number of meningococcus carriers that have been detected the recorded incidence of cerebro-spinal fever has been infinitesimal.

ORGANIC PARAPLEGIA DUE TO LIGHTNING STROKE.

PARALYSES are not rare in persons who have survived being struck by lightning. They are, however, commonly functional paralyses, and have a good prognosis. A. Porot¹ has recently described three cases in which the physical signs pointed to organic rather than functional paraplegia due to lightning stroke. The patients were Serbian soldiers. In August, 1916, on the Macedonian front a number of these men were reposing under a tree during a thunderstorm, in spite of the general belief that it is unwise to take cover under trees during thunderstorms, when the lightning struck and killed four of them. Others were struck and survived, and two of these were under the author's charge six and eight months after the accident. One had very extensive scars of burns on the right chest, iliac fossa, thigh, and knee. He was unable to stand or walk, exhibiting intense spasmodic paraplegia, with much wasting of the muscles, particularly in the left thigh and right leg. The left quadriceps extensor showed clonic spasms while at rest; there was patellar clonus and an extensor plantar reflex on the right side, while no plantar reflex could be obtained on the left. On both sides the abdominal and cremasteric reflexes were increased. Both legs were insensitive to touch, pain, and heat up to a level some two inches above the patella, and there was similar hypo-aesthesia of the trunk and arms up to the base of the neck. The sphincters were not involved. The second patient was less badly burned, and, by May, 1917, had to a great extent recovered. He still exhibited, however, permanent diminution of sensation (touch, pain, and heat) in various areas of the left leg, especially those supplied by the second lumbar and first and second sacral segments, with loss of sensibility to heat in the same areas on the right. The third patient, who was not under Dr. Porot's charge, had not lost his senses when he was struck (as the other two had), but was suddenly seized with paralysis while marching next day. By June, 1917, he had greatly improved, but showed much increased reflexes, ankle clonus on both sides, patellar clonus, and a feeble extensor plantar reflex on the left. He also had a traumatic cataract in the right eye, dating from the accident.

Medical Notes in Parliament.

Army Medical Service in France: Committee of Inquiry's Report.—Major David Davies asked Mr. Macpherson whether the Committee of Inquiry presided over by General Sir Francis Howard had now concluded its labours; and whether it was proposed to give any information to the House in regard to the questions upon which it had reported. Mr. Macpherson said the report had been received and was now under consideration. He was not in a position to make any statement. Major Chapple asked whether the War Secretary would institute periodic conferences of medical officers representative of the staffs in the various commands in order to discuss matters connected with the efficient and economical administration of medical officers. Mr. Forster replied that there existed already a special machinery for this purpose in the War Office, and this was in close touch with the hospitals and staffs of command and in communication with the Food Controller.

Hospital Treatment of Discharged Disabled Men.—In reply to Lord Henry Cavendish-Bentinck, Sir Arthur Griffith-Boscawen, Parliamentary Secretary to the Ministry of Pensions, repeated the information given by Mr. Hodge to Sir Henry Harris, as published last week (p. 128), and added that the Ministry of Pensions was taking steps to provide institutions. A large number of beds was available for the neurasthenic, epileptic and paraplegic, and for advanced cases of tuberculosis. Three orthopaedic clinics had been opened in Glasgow for out-patients, and a large number of similar institutions was being established in all parts of the country. In reply to Mr. Richards, on January 23th, Mr. Hodge said that the number of disabled men at present receiving treatment in South Wales and Monmouthshire under conditions entitling them to full allowances was 418, but the total number of men under treatment, including out-patient treatment, would be substantially larger. He was unable to distinguish between those permanently and temporarily disabled. The institutions available for such treatment at present under the direct control of a Department of State in Wales numbered eighty-six, but it was given also in many civil hospitals and institutions. He hoped presently to secure another 500 beds. The South Wales Joint (Disablement) Committee possessed under the Naval and Military War Pensions Act, 1915, such functions as might be delegated to it by the constituent local committees, and these functions included that of making arrangements for treatment or training with institutions designed to serve extended areas. It was the policy of the Department to use the Joint Disablement Committees as agents for the provision and maintenance of new institutions. Mr. Hodge added that he understood that these committees got financial assistance, upon which Mr. Hugh Edwards observed that it was not to the amount they had asked for.

Military Hospitals: Officers' Pay.—Commander Bellairs asked Mr. Macpherson whether he was aware that, while Article 361 of the Royal Pay Warrant, 1914, provided for the issue of charge pay to officers in charge of a general or other hospital, or of a division of a general hospital, the War Office letter 48 A.M.C. 895 (A.M.D.1) of November 21st, 1917, limited the issue of charge pay to the officers in charge of the surgical and medical divisions only of certain hospitals; whether he was aware that the medical officer in charge of the mental division of 1,000 beds in the Lord Derby War Hospital, Warrington, had been refused charge pay, although the medical officers in charge of the medical and surgical divisions in the same hospital, of 462 and 1,538 beds respectively, were recognized as eligible for charge pay if drawing full army pay. Mr. Forster replied: The letter in question merely explained the provisions of the Royal Warrant governing the issue of charge pay. The Warrant allows charge pay for the divisions of a general hospital, and these hospitals are invariably organized into two divisions—medical and surgical—the former including all cases that are not surgical in character, and it is not proposed in this case to alter the practice of the service. The mental cases in the Lord Derby War Hospital are treated in the mental section of the medical division.

Nerve-strained Soldiers.—Mr. King asked Mr. Macpherson whether any steps had been taken in consequence of a conference held before Christmas between the War Office and certain alienists and other medical men, in which the latter had brought forward proposals for the retention under military control up to the time of complete recovery of all cases of transitory uncertifiable loss of balance due to the strain of battle; whether it was intended to provide new institutions for the treatment of such soldiers while they remained in the army, which should be mainly under the charge or supervision of lunacy experts; if so, what provision would be made in order that, if unfit for military service, they might be speedily discharged to the disablement department of the Pensions Ministry and afforded facilities, with as little risk of delay and detriment as possible, for their return to self-supporting industrial life? Mr. Macpherson said that steps were being taken to find suitable premises, and that the institutions would be provided with staffs of neurological experts.

Advisory Committee for the Blind in Scotland.—Mr. Munro announced that the composition of the Advisory Committee for the Blind in Scotland is as follows: Sir David Panlin (Chairman), Mr. J. Frew Bryden, the Rev. Thomas Burns, D.D., F.R.S.E., Mr. Alexander Butters, Mr. W. C. Long, Mr. C. G. Lothian, Miss Isabella Lyall, Mr. George Mackay, F.R.C.S., M.D., Major William Reid (Vice-Chairman), Mr. Thomas Stoddart, and Mr. W. M. Stone. The Secretary is Mr. J. B. B. Brown, of the Local Government Board for Scotland.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

MAJOR G. M. HUNT, M.C., A.A.M.C.

Major Gladstone Montague Hunt, aged 28, was killed in action while leading stretcher-bearers forward in the battle of Broodseinde Ridge. He was educated at the Sydney High School and graduated M.B., Ch.M. Sydney University in 1910. He acted as R.M.O. to the Goalburn Hospital, N.S.W., and as honorary surgeon to the Charleston District Hospital, Queensland, and the Bega District Hospital, N.S.W., after which he practised successfully at Candello, N.S.W. Receiving his commission in the A.I.F. in April, 1915, he saw service in Egypt, Gallipoli, and France. He was awarded the Military Cross early in 1917 for gallantry during the German retreat near Bapaume, and was promoted to the rank of major in June, 1917.

Died of Wounds.

MAJOR T. J. FRIZELL, A.A.M.C.

Major Thomas J. Frizell, whose death on December 2nd, 1917, aged 29, from wounds we recorded in our issue of December 15th, p. 806, was educated at the Sydney Grammar School and graduated M.B., Ch.M. at the University of Sydney in 1911. He was resident medical officer to the Sydney Hospital for two years, and at the outbreak of war was a resident officer at the Coast Infections Hospital, Sydney. He received his commission in August, 1914, and served as an ambulance officer in Gallipoli and in France. He was promoted to the rank of major on November 14th, 1916. While in charge of an advanced dressing station near Weshock on October 8th, 1917, he received his fatal wounds.

CAPTAIN J. R. TILLET, A.A.M.C.

Captain J. R. Tillet, whose death from wounds on October 2nd, 1917, we announced in our issue of November 3rd, 1917, p. 599, was the son of Mr. J. V. Tillet, Crown solicitor, N.S.W. He was educated at the Sydney Grammar School, and graduated M.B., Ch.M. at the Sydney University in July, 1916. After a term as R.M.O. at the Toowoomba General Hospital he was commissioned in the A.I.F. in November, 1916. After working in a base hospital in France he joined a field ambulance, and was immediately posted as M.O. to a field artillery brigade in June, 1917, with which unit he was serving when wounded. His good work has been recognized, and he was mentioned in dispatches on January 1st, 1918.

Died.

CAPTAIN F. B. METCALFE, A.A.M.C.

Captain Frank B. Metcalfe, who died on October 6th, 1917, from the effects of an injury received in France, was 26 years of age and the second son of Dr. Metcalfe of Norfolk Island. Educated at King's School, Parramatta, he entered St. Paul's College, Sydney University, and graduated M.B., Ch.M. in July, 1916. After holding the appointment of resident medical officer to the Children's Hospital, Brisbane, he received his commission in the A.I.F. in October, 1916, and proceeded overseas, where he received the injury that caused his death. He was a fine footballer and very popular among his fellow-students and officers.

Wounded.

Captain T. Martin, R.A.M.C. (temporary).
Captain J. L. Pearse, R.A.M.C. (temporary).
Captain T. C. Storey, R.A.M.C. (S.R.).

Prisoners of War.

Captain A. G. Bryce, R.A.M.C. (temporary).
Captain H. B. Goulding, R.A.M.C. (S.R.).

Formerly Reported Wounded, now Reported Not Wounded.

Captain D. R. Alexander, R.A.M.C. (temporary).

DEATH OF SON OF MEDICAL MAN.

Floyd, William Eric, Probationary Flight Officer, Royal Naval Air Service, eldest son of Dr. W. E. Floyd, of Claughton, Birkenhead, killed in a flying accident, January 21st, aged 18.

MEDICAL STUDENT.

Croft, Eric, M.C., Captain Royal Field Artillery, killed by a fall over banisters in a London hotel on January 16th, aged 26. He was a medical student at the London Hospital before the war, and came to join from Dunedin, New Zealand. He had been gassed at the front, and had gained the Military Cross.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

FOREIGN DECORATIONS.

A list of decorations recently awarded by the King of Serbia for distinguished services rendered during the campaign includes the following medical officers, all of whom belong to the A.M.S. or R.A.M.C. unless otherwise indicated:

ORDER OF ST. SAVA.

2nd Class. Surgeon-General Sir H. R. Whitehead, K.C.B., Director of Medical Services, British Salonica Force.

3rd Class.—Colonels: S. F. Clark, A. A. Sutton, C.B., D.S.O. Temporary Colonels: Sir T. Crisp English, K.C.M.G., Sir J. Purves Stewart, K.C.M.G. Lieut.-Colonels: F. J. Brakenridge, C.M.G., H. J. M. Buist, D.S.O., B. Forde, C.M.G., A. G. Hay. Major (temporary Lieut.-Colonel) A. E. Kidd.

4th Class.—Majors J. T. Johnson, D.S.O., H. Rutherford, F. A. Stephens, D.S.O., H. Walker, W. J. Weston, D.S.O. Brevet Major D. M. Corbett. Temporary Majors G. P. Mills, K. W. Monsarrat, L. G. Parsons. Captains: A. E. Barnes, E. J. Y. Brash, B. L. Davis, H. W. Farebrother, J. Fenton, R. Fullarton, W. R. Galwey, M.C., A. W. Harrington, A. B. Jameson, P. H. Mitchiner, A. R. Moodie, W. L. Murphy, R. V. Slattery, W. A. Valentine. Temporary Captains F. M. Bishop, R. D. Fitzgerald, C. Y. Flewitt, A. A. Greenwood, W. Haward, C. O. Stallybrass, L. D. Woods. Temporary Lieutenant B. W. Howell, and Dr. Harold W. Wiltshire, one of the teachers in clinical medicine at the Royal Army Medical College.

5th Class.—Captain H. J. Shields, C.A.M.C.; temporary Lieutenants J. N. McTurk, H. C. Terry, J. H. Watson; temporary Quartermaster and honorary Major H. H. Taylor; temporary Quartermasters and honorary Lieutenants H. J. Angell, J. Fraser, F. W. Sharpe.

ORDER OF THE WHITE EAGLE.

4th Class.—Lieut.-Colonel G. Gow, Canadian Army Dental Corps, Canadian General Hospital.

MENTIONED IN DISPATCH.

The name of Major (now Brevet Lieut.-Colonel) L. J. M. Deas, I.M.S., has been added to the list of officers mentioned by General Sir Percy Lake, K.C.B., K.C.M.G., in his dispatch of October 19th, 1916, whose services were deserving of special mention.

NOTES.

Captain H. E. Gamlen, M.B., B.S., 11th General Hospital, has been appointed to be Consulting Radiographer for the British Expeditionary Force in Italy.

Dr. R. Arderne Wilson, of Guernsey, has been appointed Surgeon to the Serbian Relief Fund on the Salonica front and second in command.

ALLOCATION OF ORTHOPAEDIC CASES TO CENTRES AND HOSPITALS.

The Army Council has issued an Instruction directing that all military orthopaedic cases transferred to this country from overseas shall in future be sent direct to a military orthopaedic centre, or to a hospital approved by the consulting surgeons or other officers. Such patients are not on any account to be distributed from railway stations to auxiliary and other hospitals. In all the commands at home orthopaedic centres have been established, or special hospital accommodation provided. The order does not apply to men belonging to the Canadian, Australian, or New Zealand contingents, who will be dealt with as notified in previous orders.

VILLAGE SETTLEMENTS FOR DISABLED MEN.

In a paragraph entitled "Garden Cities for Disabled Men" an account was given (JOURNAL, November 17th, 1917, p. 666) of the proposals of a committee, of which Dr. R. Fortescue-Fox is chairman, for the establishment of village settlements for the cure and training of disabled ex-service men. The scheme has, we are informed, received the approval of the Ministry of Pensions so far as treatment and training are concerned, but the settlement of men in village communities, which is the ultimate aim of the committee, not only as a measure of social reconstruction but as a powerful attraction to the men themselves, is not considered by the Ministry to be within its present scope. It will grant the usual allowances for treatment and training. It is proposed to take steps at once to provide a village centre for the London district. The committee is now seeking funds for the purchase of a suitable site. Its honorary secretaries are Lady Grogan and Miss Hilda Fox, 36, Devonshire Place, W.1, and the treasurer is Mr. W. Cecil Harris.

Correspondence.

THE CO-ORDINATION OF BRITISH MEDICAL POLICY.

SIR,—May I ask whether, as a profession, we have any definite political policy respecting legislation that is likely to be brought before Parliament in the near future? Do we know what we want? What do we consider best for the nation? Are we sure our opinions have not been based on what is best for ourselves? Or have we decided to obtain a report from a committee which will be sent wandering about between Executive, Divisions, Representative Body, and Committee until Parliament has decided for us what we are to have?

It appears probable that a Ministry of Health will be set up in the near future, a National Health Amendment Bill is overdue, and there is also an Infant Welfare Bill in the offing. The first of these might well be one of the most important medical Acts ever passed. The Insurance Act will probably extend the medical benefits to dependants. Here alone we require to have a general policy which will cover changes that may take years to bring about, or may, in the changed temper of the times, be brought about in a short time. It is no use to say men are away at the war and we cannot form a policy without them; time is too precious, we cannot be too prepared. We must also remember that there is a probability of a Labour Government in the not far distant future.

May I draw attention to another point? When the daily papers discuss probable changes they give the opinions of the "societies" or the Insurance Commissioners—of any one but the medical profession. Why? Why is it so dreadful for a medical man to discuss medical politics in a lay paper, even under a *nom de plume*? Methinks if we ignored the daily press less we might be less ignored. Are we content to be nonentities? Why be satisfied with being told what is good for you by people who know nothing about you?—I am, etc.,

Mumbles, Glamorgan, Jan. 28th.

F. DE COVERLY VEALE.

THE PULSE PRESSURE TEST BEFORE OPERATIONS.

SIR,—Will you permit an anaesthetist to utter a warm welcome to a few words from a physician such as he has long hoped to hear? In your issue of January 19th, p. 101, Sir J. Mackenzie writes: "So many bogeys have been raised at one time or another about the heart being unable to stand anaesthetics," and these are the words to which I refer. They cheer one heart at least, and they will, I hope, save many others from unmerited condemnation. My experience has not presumably been unusual in this matter, and it is that I have on a great many occasions given anaesthetics with perfect safety and but little anxiety to persons who had been assured that "their hearts could not stand it." I am certain that the opinion is much too frequently given that a patient must not have an anaesthetic "on account of his heart." When given, it tends by the alarm it raises to put into a position of peril the person who would otherwise have run none but the average risk of anaesthesia. The condition of the heart, as evinced by ordinary clinical signs, plays by no means the leading part in anaesthesia that is commonly assigned to it by those who are not constantly giving anaesthetics or attending operations. Every variety of valvular disease, for instance, has been present in one patient or another who has safely passed through anaesthesia in my hands, and doubtless in the hands of any other experienced anaesthetist. Yet the mere presence of an organic murmur will in the case of many a practitioner lead him to forbid an anaesthetic, and thus, when the patient is confronted with the necessity for an operation, an additional and unnecessary anxiety is cast upon him, and the anaesthetist is called upon to dissipate fears that never should have arisen, and to give his anaesthetic under needlessly unfavourable conditions. The time will come, probably, when accurate scientific tests of the reserve power of the circulatory as well as of other systems will be applied before every major operation, and perhaps some operation fatalities will thus be avoided. In the meantime it is well to bear in mind that anaesthetics,

properly chosen and given, make little call upon the heart, and that when an operation is necessary it is extremely seldom that it should be banned upon the score of cardiac risk.—I am, etc.,

London, W. Jan. 23rd.

J. BLUMFIELD.

SIR,—I have not had the opportunity of reading Dr. Cashman's article on the pulse pressure test, but I feel qualified to ask a little space to state my views on the matter because I made a large number of tests myself some years ago, and came to the conclusion, and am still of the opinion, that variations in blood pressure, as a result of change in bodily position, or bodily exertion, have no value whatever as a test for the efficiency of the heart. I made trials on ninety healthy industrial school boys, and found that those in the first athletic squad gave such changes in pulse pressure, that had the test been a reliable one, they ought to have died from cardiac failure there and then.

I also made tests in the out-patient department at Mount Vernon Hospital, when I was acting as clinical assistant to Sir James Mackenzie, on a large number of old people with signs of cardiac failure, and I found in most of them that the difference in systolic and diastolic pressure reading after exertion indicated that they had strong hearts, although nearly all of them showed marked symptoms of cardiac failure brought out by the exertion.

I therefore say that when a supposed test for the reserve power of the heart indicates heart failure in a group of trained athletes and a large reserve of power in hearts on the verge of failing, it is a worthless and dangerous criterion.—I am, etc.,

Southall, Middlesex, Jan. 26th.

J. DAVENPORT-WINDLE.

VINCENT'S ANGINA.

SIR,—There seems to have been enough correspondence on the subject of Vincent's angina and associated stomatitis and gingivitis to warrant your publishing finally when and where the first observations on this disease were made, as occurring amongst British troops.

In vol. ix (1916) of the *Proceedings* of the Royal Society of Medicine a report was presented by me, and again published in the *BRITISH MEDICAL JOURNAL* of March 1st, 1916. Nine months later Taylor and McKinstry read a paper on the same subject, making practically the same observations, and came to the same conclusions. My paper, as it appeared in the *BRITISH MEDICAL JOURNAL*, was published in the form of an official pamphlet to be issued to medical officers of the Canadian forces, by the D.M.S., Canadians.

In the *BRITISH MEDICAL JOURNAL* of January 19th, Taylor and McKinstry have published an article on the serology of the condition, which was discussed by me previously, and which they have quoted.

The condition is still very prevalent, but it would seem to me that if correspondents would familiarize themselves with the literature, much space taken up with such discussion would be saved.—I am, etc.,

F. B. BOWMAN,

No. 1 Canadian General Laboratory,
Folkestone, Jan. 24th.

Major C.A.M.C.

THE DISTRIBUTION OF TRYPANOSOMIASIS.

SIR,—In the *JOURNAL* of July 28th, 1917, page 164, Sir Patrick Manson states, in regard to the human trypanosomiasis due to infection by *T. rhodesiense*, that "it appears to be confined to Rhodesia particularly, but not entirely to the north of the Zambesi."

I feel that this observation, as it is so definite in form, should not be allowed to go unchallenged. Trypanosomiasis due to *T. rhodesiense* is endemic in Nyasaland, as was first shown by Stannus and Yorke,¹ also in German and Portuguese East Africa, to the east of Lake Nyasa, as demonstrated by Taute. This disease has, therefore, a very much more widely spread distribution than is indicated by Manson.—I am, etc.,

H. S. STANNUS.

Conquered Territory, German East Africa,
Oct. 29th, 1917.

Obituary.

HENRY MAUDSLEY, M.D., F.R.C.P.,

FORMERLY PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY COLLEGE, LONDON.

HENRY MAUDSLEY came of a yeoman family long settled in Yorkshire near the border of Lancashire. He was born on February 5th, 1835, the third son and fourth child of Thomas Maudsley of Rome, near Settle, Yorkshire. He attended Giggleswick School, but when twelve or thirteen, at the suggestion of his uncle, Dr. Bateson, at one time medical officer of health for Southwark, he went as a private pupil to Mr. Newth of Oundle, Northamptonshire. From there he matriculated in due course at the University of London, and, again on the advice of Dr. Bateson, was apprenticed to the apothecary at University College Hospital, Mr. Clover, afterwards the well-known anaesthetist. His career at University College and in the University of London was very distinguished. He was the first in most class competitions, and carried off ten gold medals; he also took the University Scholarship and gold medal in surgery when he graduated M.B.Lond. in 1856. Still he was not reckoned a diligent student, and often seemed to his teachers less interested in science than in sport, becoming, indeed, an authority on cricket. But his brilliant intellect carried all before it. At first he thought of becoming a surgeon, and was house-surgeon at University College Hospital to Mr. Quain; afterwards he contemplated entering the Indian Medical Service, and in order to fulfil the regulation requiring candidates at the examination to have had experience in lunacy, he took an appointment in the Essex County Asylum. This accidental circumstance may be said to have determined his career, for after a short period at the Wakefield Asylum he became, at the age of 24, medical superintendent to the Manchester Royal Lunatic Asylum, Cheadle, in 1859, an appointment which he retained until 1862, when he went to London to try his fortune. He had already written some essays, including one on "Hamlet," which had attracted the notice of Dr. John Conolly, who at that time was superintendent of Hanwell Asylum; he had a small private asylum near by, and Maudsley was resident physician there for a time, and afterwards married Conolly's youngest daughter. Soon after settling in London Maudsley was appointed editor of the *Journal of Mental Science*. Two years later he became physician to the West London Hospital, Hammersmith. He was appointed professor of medical jurisprudence at University College, London, in 1869, and retained the chair until 1879. He early attained success in the practice of his speciality, and contemporaneously became well known as a writer, by a series of books which were not only of high technical distinction but appealed to the more thoughtful section of the general public. In 1866 he published his first large book on the *Physiology and Pathology of Mind*, which has been described as epoch making. In 1874 he published a book on responsibility in mental disease. Afterwards he rewrote his early book, and issued it in two separate volumes, the one in 1876, on the physiology of mind, and the other in 1879, on the pathology of mind; this last volume reached a second edition in 1895. In 1883 he published *Body and Will*, and in 1886 *Natural Causes and Supernatural Seemings*, a book which reached its third edition in 1897. Another book was *Life in Mind and Conduct* (1902), and his final work, which may be said to embody the philosophy of his long life, entitled *Organic to Human, Psychological and Sociological*, appeared in 1917.

He became a Fellow of the Royal College of Physicians in 1869, and we believe was at the time of his death, both by age and seniority, the fourth on the list. He delivered the Goulstonian Lectures in 1870 on body and mind. He received the honorary degree of LL.D. Edin. in 1884, and was an honorary member of the Medico-Psychological Society of Paris, of the Imperial Society of Physicians, Vienna, and of the Medico-Legal Society of New York.

His interest in the work of the British Medical Association is shown by the fact that he was vice-president of the Section of Psychology at the annual meeting in Newcastle in 1870 and president of the same section at the annual meeting at Birmingham in 1872. In 1905 he delivered the address in medicine at the annual meeting

at Leicester. This address covered a wide field and contained the germs of his later book, for he looked forward then to the ultimate levelling of all artificial partitions, to the recognition of inorganic, of organic, and of spiritual nature as grades in a continuous scheme woven together by the golden thread of evolution. But it also dealt in a philosophic spirit with the practical problems underlying the prophylaxis of disease, for, specialist though he was, Dr. Maudsley took care to keep himself acquainted with all movements in medicine.

Dr. Maudsley may be said to have retired from practice in 1903, when he paid a visit to Australia for the purpose, as he said, of "seeing how cricket was played." He retained his mental faculties and the clearness of his intellect to the very last, and had just finished the revision of the proofs of a volume of essays. He had been failing in health for some two or three months, but died peacefully in his chair on January 24th after a few weeks of confinement to his house overlooking Bushey Heath, not far from Harrow, one of the last of the untouched heaths near London.

We are indebted to Dr. F. W. Mott, F.R.S., for the following tribute to Dr. Maudsley's life and work.

By F. W. MOTT, F.R.S.

At the age of 30 Maudsley's philosophical mind revealed itself to the general public by the publication in the *Westminster Review* of a remarkable essay on "Hamlet." He had been previously known to the profession by a number of original articles in the *Journal of Mental Science* under Dr. Bucknill's editorship, by whom he was nicknamed "the young philosopher." Is it not strange to know that he harked back to his grandfather, who was notable in the countryside for his sayings, sardonic and sarcastic, which had earned him the sobriquet of "the old philosopher." Henry Maudsley's next most notable work was *The Physiology and Pathology of Mind*, published in 1867; and as early as this he declared his aim to be—

To treat of mental phenomena from a physiological rather than from a metaphysical point of view, and to bring the manifold instructive instances presented by the unsound mind to bear upon the interpretation of the obscure problems of mental science. Also to do what he could to put a happy end to the inauspicious divorce between the physiology and pathology of mind.

I was informed by a very eminent physician that upon reading that work when he was studying philosophy and law as a young man at Oxford, he determined to take up medicine, and especially that branch relating to disease of the nervous system. Thus the seed soon fell on fruitful ground, and during the last generation Maudsley's name has been pre-eminent in all that pertains to mental science. Indeed, it would repay the present generation to read his later separate works on the *Physiology of Mind* and the *Pathology of Mind*, which are referred to frequently by Charles Darwin and by Ribot, and many other great contemporaries of his. William James, the author of *Principles of Psychology*, recommended his students to read Maudsley's *Pathology of Mind*. One of the most interesting chapters I know, and from which I have gained much valuable information, is on "the emotions or affections of mind." It is prescient and original in thought, and is particularly interesting at the present time when emotional stress is operating on a large part of civilized humanity. One passage in relation to modern conditions of shell shock may be noted:

To all appearances a violent emotion may react as a strong physical shock to the nervous system, for it may produce convulsions, fainting, loss of sensation, paralysis of movement, deafness, exactly the effects which a strong electric shock may produce. We have not then to do with mysterious self-determining agencies, we have to do with phenomena which, complex as they are, will eventually receive a complete analysis.

In a copy of this work which he presented to me he said: "The quotation-notes at the end of chapters might at any rate be interesting." These quotations and the references show his extraordinary knowledge and wide reading in philosophy, whence he got the broad grasp of science as applied to the physiology and pathology of mind, and how he has analysed and woven these into his work in a most lucid and convincing way, so that it has become his own fabric, and not a patchwork of ideas and thoughts of others.

The same might be said of his book *The Pathology of Mind. Responsibility in Mental Disease* was another

work which aroused a great deal of attention and was regarded as a standard book on account of its practical application to medico legal questions relating to insanity, crime, and responsibility. When Dr. Maudsley was lecturer on medical jurisprudence at University College I well remember his coming in and reading a case of mistaken identity from the *Times* and commenting upon it in a way that immediately attracted the attention of the students by his originality, humour, and critical insight. His latest work, *Organic to Human*, embodies his philosophy, which may be summed up in the principle of unity of the human organism and its continuity with the rest of Nature's processes. Borrowing his own words, it may be said that having done diligently the work which it came in his way to do for a livelihood and fulfilled his life-function in the sincere utterance of himself Maudsley has left his philosophical and philanthropic work to the fate of time and events, well knowing that when all is said—

Thought is the slave of life and life the fool of time,
And time that takes survey of all the world
Will have a stop.

The Maudsley Hospital.

Dr. Maudsley in 1907 communicated to me his desire to give £30,000 to the London County Council if it would build a hospital for the study and treatment of acute mental cases. I mentioned the matter to Sir John McDougall, who pointed out to me the desirability of such a hospital being associated with the University of London; consequently I drew up a scheme, and this was supported by Mr. Balfour and Sir Arthur Rücker, the late principal of the university. The offer was then communicated privately to the chairman of the London County Council, and in December, 1907, Dr. Henry Maudsley put before Mr. H. P. Harris, who was then chairman, his scheme for the establishment of a fully equipped hospital for mental diseases in London. Towards the cost of carrying it into effect Dr. Maudsley offered to contribute a sum of £30,000. In a letter to Mr. Harris, dated February 14th, 1908, Dr. Maudsley said that as a physician who had been engaged in the study and treatment of mental diseases for more than fifty years, he had been deeply impressed with the necessity of a hospital whose main objects should be the early treatment of cases of acute mental disorder, with the view as far as possible of obviating the necessity of sending them to the county asylums; the promotion of exact scientific research into the causes and pathology of insanity, with the hope that much may yet be done for its prevention and successful treatment; and the provision of an educational institution which should offer to medical students the opportunities of getting good clinical instruction in a class of diseases of which under existing conditions it is not easy for them to obtain a competent knowledge. Dr. Maudsley's gift was accepted, but much delay occurred before a site was finally chosen at Denmark Hill, opposite the new King's College Hospital. The following statement submitted by the London County Council to the Royal Commission on University Education, 1913, as to clinical instruction in special hospitals, may with advantage be quoted from the final report of the Commissioners:

In addition to the advantages which it is expected will ensue to the patients who are treated there, it is hoped that the hospital will prove of great value in the dissemination of knowledge of mental diseases and in the provision of systematic instruction in methods of treatment. The proposal includes the provision of a department for pathological research, which, it is suggested, would be accomplished most economically by the removal of the staff and equipment of the Claybury Laboratory to the new institution. It is hoped that this institution, when in being, will be in close touch with the London University and medical schools.

The hospital was not finished when the war broke out, but to the 4th London General Hospital, of which King's College Hospital is the nucleus, the London County Council not only handed over two large Grove Lane schools, but in addition hastened the completion of the Maudsley Hospital, the whole being placed in connexion and forming the Maudsley extension of the 4th London General Hospital. For the past two years or more this has formed the neurological section, and served as a clearing hospital, and for the treatment of cases of shell shock and war psychoneuroses. It has already fulfilled a most useful purpose, which, it is to be hoped, may be extended to the civil population after the war is

over. We only regret that Dr. Maudsley did not live to see this practical application of his life work and principles.

Some Personal Reminiscences.

In connexion with the planning, building, and future objects of the hospital, I had many opportunities of becoming personally and intimately acquainted with Dr. Maudsley, and I made frequent visits to Bushey Heath. It was a great pleasure and intellectual treat to talk with the grand old philosopher, and after dining and spending the evening with him, I would come away sometimes humbled but always mentally refreshed. No matter what subject we talked upon I always learnt from him; even upon technical matters of which I had more knowledge and experience, I would find his keen, critical mind ready to detect weak points in the argument, but his sound judgement seemed intuitively to tell him when the facts were adequate to support a proposition.

To those who had not the privilege of knowing him intimately he might seem cynical and satirical, but beneath a seeming hypercritical manner was a most kindly disposition. I cannot help thinking that at times the tinge of pessimism which he generally showed was partly due to his having no children, and partly to an inborn trait; for he told me that he believed a man may inherit two unblended temperaments, and that it was so in his case.

His knowledge of character, derived from long experience and contact with men in all ranks of society in his professional capacity and otherwise, made his conversation upon politics and social problems most interesting and entertaining, for it revealed a keen insight into human conduct, and the motives activating it.

He had a great love of Nature, and up to a few years ago he worked industriously in his garden, but he had no taste for music; although he possessed the sense of rhythm, that of melody was lacking.

Up to the very end he retained all his remarkable mental faculties, and his memory was marvellous; for he would quote long passages from the great authors and poets, and show that he still kept abreast with the general principles underlying modern biological science.

SIR GEORGE HARE PHILIPSON, M.D., F.R.C.P.,

CONSULTING PHYSICIAN, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE; EX-PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

The announcement of the death of Sir George Hare Philipson will cause deep regret to many members of the medical profession. Although age had begun to tell upon him lately, he yet looked the picture of health, and seemed as if he might have had several years of useful work before him. He died literally in harness and in a manner which, if choice had been granted him, he would probably have preferred. On January 22nd he presided at a meeting of Council in the College of Medicine and next day was out and about as usual, but towards the evening he did not appear to be quite well. When the butler called his master at 6.45 a.m. on January 24th he found him in bed in a condition of unconsciousness. Dr. J. R. Baumgartner, a near neighbour and an old friend, was at once summoned, and shortly afterwards his colleague and intimate friend, Sir Thomas Oliver, was called in consultation. Their patient, who had somewhat rallied from the shock, was still in a condition of incomplete coma, from which he could only be partially roused, but the paralysed right arm, leg, and face all too clearly pointed to the fact that a serious cerebral haemorrhage had taken place. The coma deepened, and at 10.45 the same evening Sir George breathed his last. His nephew, Mr. John Philipson, was in close attendance upon him, as also his butler, to whom, after twenty-eight years' service, he was much attached.

Sir George Philipson, who was a bachelor, belonged to an old Newcastle family. He was proud of his origin, of the city of his birth, and of the county of Northumberland. A son of the late Mr. George Hare Philipson of the firm of Messrs. Atkinson and Philipson, carriage builders, Newcastle, he was born on May 18th, 1836. At the time of his death he was, therefore, nearly 82 years of age. He was educated at University College, London, and at Gonville and Caius College, Cambridge; he graduated B.A. with honours in the Natural Science Tripos and took the M.B. in 1862; in 1865 he proceeded to the higher degrees in

arts and medicine. In 1873 he became a Fellow of the Royal College of Physicians. He was an Hon. D.O.L. of Durham University and LL.D. of Glasgow.

Although Sir George in his earlier years wrote several papers on medical subjects and gave the Bradshaw Lecture at the Royal College of Physicians in 1884 and was held in high esteem in the North of England as a consulting physician, his best work, and that for which he will be longest held in grateful remembrance, was done in and for the Royal Victoria Infirmary and for the medical charities of his native city. His appointment as physician to the infirmary dates back to April, 1868, but for four years previous to this he had acted as pathologist to the institution. It was a fitting recognition of his fifty years' service to the infirmary that in 1915 he was presented by the staff and the house committee with some silver plate. The duties of the office of chairman of committee he continued to discharge. He was an excellent chairman—patient in listening to other speakers and sound in giving advice. He took an active part in the building of the new infirmary. At the laying of the foundation stone, owing to the illness of the chairman, it fell to Sir George Philipson as vice-chairman to receive King Edward, then Prince of Wales, and to read the address of welcome. It was a proper sequel to this event that when, a few years later, the new infirmary was opened he should again have been brought into close association with His Majesty. Sir George received the honour of knighthood in 1900. He was a distinguished Freemason. He did not join the craft until well on in life, for it was in 1890 that he was inducted into the Universities Lodge. Rapidly passing through the Chairs he became Prov. S.G.W. of Durham in 1891, and two years afterwards he was largely instrumental in founding the University of Durham Lodge.

He was the representative of the University of Durham on the General Medical Council since 1892, and although he rarely took part in the discussions of that body, he was a most useful member of its committees.

By his death Newcastle and the North of England have sustained a great loss. There were few movements of a medical and philanthropic nature with which his name was not associated. He was extremely methodical and punctilious. One of his most striking features was his courteous manner. In matters of ceremony he was unsurpassed as regards knowledge of procedure and precedence. To all ceremonial events he lent a particular grace and dignity. His treatment of all persons, irrespective of rank and social worth, was alike gentle and considerate. Behind an old-time manner which was peculiarly his own, there was yet a strength of will which could make itself felt when occasion required. For over four decades he occupied the Chair of Medicine in the University of Durham. When vice-chancellor of the university it fell to his lot to induct into office the present chancellor, the Duke of Northumberland.

He was an active member of the British Medical Association. For fifteen years he acted as local secretary, a post he vacated on being made president of the Branch. At the Worcester meeting of the Association he was a vice-president of the Section of Medicine. He occupied the presidential chair when the Association met in Newcastle in 1893. Those members of the profession who attended the public meeting in Newcastle to listen to the president's address may remember how, on the occasion of welcoming on the platform the colonial and foreign delegates, there occurred a contest of courtesies between himself and Professor Pozzi, of Paris. It was a trial of bowing acknowledgements, and as to whom the last bow would belong. Notwithstanding the deference and the politeness of the Frenchman, Sir George had the last bow, at which the meeting cheered, Newcastle having won. In this little episode was exhibited that urbanity which was so strikingly his own.

A special memorial service was held at St. Nicholas Cathedral on Monday last which was attended by the Lord Mayor and the Corporation, the city magistrates, the professors of the University of Durham, of the College of Medicine, and Armstrong College; by the graduates and undergraduates of the university, the medical profession, representatives of the various medical charities with which he was connected, as well as by officers and men of the O.T.C. in khaki. The body was carried shoulder high by students of the College of Medicine from the cemetery gates to the family vault.—T. O.

SIR JAMES ALEXANDER RUSSELL, M.D., LL.D., F.R.C.P.E., F.R.S.E.,

ONE-TIME LORD PROVOST OF EDINBURGH.

JAMES ALEXANDER RUSSELL, a son of the manse and born in Argyllshire in 1846, was 21 when he graduated with honours in the University of Edinburgh, a time when the chairs were adorned by Syme, Simpson, Bennett, and Christison, but it was Goodsir who impressed him most. It was to anatomy, therefore, that he attached himself; he remained assistant and demonstrator with Turner in the university till 1876. Those who remember him recall him as a keen student, fond of all sorts of scientific problems, careful and exact in argument, and ready of speech. It was perhaps on account of these attainments that he left the serene atmosphere of the university for the more active and troubled sphere of municipal and general politics.

Though he early severed his immediate connexion with medicine, yet throughout his life he maintained a most profound interest in medical and scientific problems, and perhaps in the part he chose he did as much for the progress of medicine in the city of Edinburgh as many of those who remained entirely devoted to purely professional work.

Before entering on municipal work he studied sanitation for two years in France, and acquired a fluency in the language which stood him in good stead in after years. On his return he delivered a series of lectures on sanitation, which perhaps more than anything else brought him in touch with his future work. When he entered on municipal work he was an instant success. His intimate knowledge of medicine, public health, and sanitation placed him at once on a platform above his colleagues, and gave him a unique opportunity of serving his city, of which he made ample use. The work in the improvements of housing and sanitation generally in the city, much of which was carried out on his initiative, remains a monument to his capacity and industry, and has done much to raise the moral and social status of Edinburgh.

Russell entered the town council of Edinburgh in 1880. He became a member and afterwards chairman of the health committee, and during his tenure of office the health and amenity of the city improved immensely. He undertook the organization of the New Fever Hospital, which is one of the largest and best equipped in the kingdom. He devoted himself heart and soul to health work, and gradually rose in the council from one position to another, until he ultimately reached the civic chair, which he adorned for the usual term. During his occupancy of that chair the profession of medicine in Edinburgh came to its kingdom, for to every medical institution and to all medical charities he gave not only his own personal encouragement as Lord Provost, but that of the civic authorities as well; and the members of the profession themselves enjoyed his generous hospitality. He was amongst the first, if not the very first, medical Lord Provost of Edinburgh, and it would be a very great advantage to that city, and not to that city only, if men of his calibre, with his scientific and medical knowledge, who had leisure at their disposal, would grace such chairs again.

The university, recognizing his great work in regard to the fever hospital and the clearing of the city of many of the more objectionable slums, as well as his work in sanitation generally, conferred on him the degree of LL.D., and shortly after Queen Victoria bestowed on him the honour of knighthood. He was an active Fellow of the Royal Society of Edinburgh and took a keen interest in its work and debates. He was also a Fellow of and examiner in the Royal College of Physicians. Russell kept up his relation with anatomy to the very last, because for a long period of years he was inspector of anatomy and vivisection for the whole of Scotland—an appointment which involved often much delicate work, and which he performed with his usual tact and ability.

He was not a very prolific writer, but he wrote two excellent papers—the one on the Morse alphabet and the other on sanitary houses—and made several contributions to the Royal Society of Edinburgh.

In politics he was a Liberal. He was most genial and kind-hearted, whether at a board meeting, a social party, or in private, and, what is most important in a public man, he was most easy of approach.

On previous occasions he had suffered from bronchitis,

and to this, along with heart failure, he succumbed on January 22nd, after four days' illness.

Sir James Russell was twice married, and is survived by Lady Russell and one daughter. He was buried in the Dean Cemetery, the last resting place of so many of Edinburgh's honoured citizens.

H. C.

CHARLES TEMPLEMAN, M.D., D.Sc.,
M.O.H. DUNDEE.

WE regret to announce the sudden death of Dr. Templeman on January 20th, at the age of 59. He was a native of Blairgowrie and was educated at Dundee High School, where he was medallist in classics, and at Edinburgh University, where he graduated M.B., C.M. in 1879, and subsequently became M.D. and D.Sc. in Public Health. He was resident to Professor Annandale and later in Dundee Royal Infirmary, to which he afterwards became visiting surgeon. After a period of general practice, he, over twenty years ago, became medical officer of health and police surgeon as a whole-time official. He was also lecturer in Medical Jurisprudence and Public Health in the University of St. Andrews. At the time of his appointment the department of the sanitary inspector was separate from the health office, and in the co-ordination of the two departments and in the multifarious developments which the preventive services have undergone since then Dr. Templeman took an active and highly-appreciated part. As a friend Dr. Templeman was distinguished by his geniality and hospitality, as a colleague he was valued for his keenness in his own work and for his tact and readiness to co-operate and to assist in those relations which brought contact with his fellows, and as a teacher he was appreciated for his clearness, for the conscientiousness with which he met his duties, and for the wealth of illustration which his long experience as police surgeon furnished for illuminating the technicalities of medico-legal affairs. He secured early and maintained the regard of his local authority as a competent, cautious, and wise officer, of wide outlook and progressive spirit.

DR. FRANK ROTHERA, who died on January 5th from double pneumonia, aged 56, was the youngest son of the late Mr. George B. Rothera, solicitor, of Nottingham. He received his medical education at Edinburgh University, and graduated M.B., C.M. in 1883 and M.D. in 1887; he also took the diploma of M.R.C.S.Eng. in 1885. After a short experience in general practice in Devonshire, Dr. Rothera settled at Beeston, where he was eventually appointed medical officer to the Beeston Urban District Council, which post he held at the time of his death. He was a member of the Nottingham Division of the British Medical Association.

THE sudden death of Dr. CHARLES VALLANCE VEREKER whilst returning from visiting a patient caused universal regret in Woolton, where he had practised for many years. He was the son of the chief cashier of the Bank of Ireland, was born in Dublin, and studied at Carmichael College, Dublin. After taking the diplomas of L.R.C.P. and S.I. in 1890 he became resident medical officer at Adelaide Hospital in the same city. Two years afterwards he settled in practice in Woolton, then a residential suburb of Liverpool, and became a member of the Liverpool Medical Institution in 1892. Dr. Vereker was a capable practitioner, and to a cheery exterior added a personal charm which, as an appreciative notice in the *Liverpool Daily Post* stated, made all his patients his friends. He was M.O.H. for Woolton and honorary medical officer to the Woolton Military Auxiliary Hospital. Dr. Vereker was not married, but leaves two brothers and many sorrowing friends to mourn his loss.

WE regret to announce the death on January 18th, from pneumonia, of Mr. FERGUS MENTFITH OGILVIE, F.R.C.S., of 72, Woodstock Road, Oxford. Mr. Ogilvie was the son of the late Alexander Ogilvie, of Sizewell House, Suffolk. He received his medical education at Cambridge University and St. George's Hospital, obtaining the M.R.C.S. and L.R.C.P. diplomas in 1888 and the F.R.C.S.Eng. ten years later. He graduated M.B., B.C. in 1890. After holding the posts of chief clinical assistant at the

Royal London Ophthalmic Hospital and the Royal Westminster Ophthalmic Hospital and ophthalmic assistant and assistant demonstrator of anatomy at St. George's Hospital, Mr. Ogilvie went to Oxford in 1899, and in the following year entered into partnership with the late Mr. R. W. Doyne, and became acting assistant surgeon to the Oxford Eye Hospital. About 1905 he retired from private practice and was appointed consulting surgeon to the hospital, where his services will be greatly missed. He contributed a number of papers to the *Transactions* of the Ophthalmological Society between 1896 and 1906. Mr. Ogilvie's mother founded the Margaret Ogilvie Readership in Ophthalmology in the University of Oxford. He was a keen fencer and a generous supporter of the Oxford Fencing Club, of which he was subsequently elected president.

LIEUTENANT-COLONEL WILLIAM HENRY QUICKE, Bombay Medical Service (retired), died in a nursing home at Reigate on January 20th, aged 59. He was educated at Westminster Hospital, took the M.R.C.S. and L.S.A. in 1880, graduated M.D.Brussels in 1882, and took the F.R.C.S.Eng. in 1896. After filling the posts of resident medical officer at Queen Charlotte's Lying-in Hospital, and of assistant obstetric physician at Westminster Hospital, he entered the I.M.S. as surgeon on March 31st, 1883, becoming surgeon-major on March 31st, 1895, and lieutenant-colonel on March 31st, 1903, and retiring on April 25th, 1911. He served in the Zhob Valley expedition on the North-West frontier of India in 1884, and was present at the affair at Daulatzai, and in the third Burmese war in 1885-86, receiving the frontier medal with a clasp. Most of his service was spent in civil employ in Bombay, where he was acting port health officer in 1888-89, and civil surgeon of Kaira in 1890-92. In April, 1893, he was appointed surgeon to the Jamsetji Jijibhai Hospital in Bombay, and professor of anatomy and curator of the Museum in the Grant Medical College, and in November, 1903, became professor of surgery and first surgeon to the hospital.

The Services.

OFFICERS, SPECIAL RESERVE AND TERRITORIAL, R.A.M.C.

A SECOND report of the Committee on the Promotion of Officers of the Special Reserve, New Armies, and Territorial Force, issued this week, deals with the promotion and rates of pay of officers of the R.A.M.C. Special Reserve and Territorial Force, and it is notified that the Government has approved and is taking action on the recommendations, with one exception. The recommendations approved are (i) that the regulations regarding increments of pay shall remain as at present, (ii) that a general list shall be introduced for the Territorial Force field ambulances and regimental medical officers, (iii) (a) that the promotion of officers belonging to general hospitals shall continue as at present, with the proviso that when *à la suite* officers leave the hospitals for other employment they shall be held supernumerary, and the consequent promotions made, and (b) that the promotion of officers belonging to sanitary companies shall continue as at present, but that a general list for sanitary companies shall be introduced at a later date, (iv) that majors R.A.M.C. (Special Reserve) shall be linked with majors of the regular R.A.M.C., and be eligible for promotion, provided they are duly recommended, when the regular officer next below them is promoted, and (v) that "the selection of officers for administrative medical positions should continue to be made from the R.A.M.C. as a whole." The recommendation of the committee not accepted by the Government was that "officers R.A.M.C. Territorial Force and Special Reserve, who joined before the war, should be put on a level with temporarily commissioned contract officers as regards pay, allowances, and gratuities, where they would gain thereby."

The recommendations, it will be seen, leave untouched some of the points to which the British Medical Association called attention in its memorandum furnished to the Committee last May. It is of interest to note that the report of the Committee contains the following paragraph: "We hope and believe that the British Medical Association and other corporate bodies concerned with the welfare of the profession will do their best to ensure that their members may suffer as little as possible in the future from their enforced absence on military service. Among

other classes and avocations there has been a similar call for material loss and sacrifice which is inseparable from any 'one-man' business, and the medical profession, though conspicuously entitled to credit and consideration, does not stand alone in this respect."

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

At a meeting of the Committee of the above fund, on January 25th, the following two cases were considered:

Widow of a captain in the Auxiliary R.A.M.C. who died in France after two years' service. Applicant is training for a nurse in a maternity hospital. Granted £10 at once and another £10 in March.

Widow of a private in the R.A.M.C. who was drowned while on active service. Left with two children, ages 2 and 4. Only income army pension. Voted £5.

Major Ewen Maclean was reappointed chairman of the committee, and Colonel Hale White and Colonel Mansell Moullin commenced their duties as honorary secretary and honorary treasurer. The committee are anxious to receive applications for the relief of the orphans of commissioned officers in the Auxiliary R.A.M.C., also from the widows and orphans of non-commissioned officers and men in the same service.

Donations and subscriptions will be gratefully received, and should be addressed to the Honorary Treasurer, at 11, Chandos Street, Cavendish Square, W.1, and all other communications to the Honorary Secretary at the same address.

EXCHANGES.

R.A.M.C.(T.F.) Captain, M.O. in charge of troops, R.A. barracks, is desirous of changing over from shore to sea duties.—Address No. 450, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

AN officer in the Southern Command wishes to exchange with one in the London district.—Address No. 449, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medical News.

COLONELS Sir T. Crisp English, K.C.M.G., A.M.S., and Sir J. Purves Stewart, K.C.M.G., C.B., A.M.S., have been appointed Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England.

THE report of the Special Committee appointed by the Central Control Board (Liquor Traffic) to inquire into the physiological effect of alcohol has been settled, and its publication is expected before the middle of February.

THE Lettsomian lectures on jaundice before the Medical Society of London will be delivered by Colonel William H. Willcox, C.B., C.M.G., A.M.S., as early as possible, and Dr. T. B. Hyslop will deliver the annual oration on May 13th at 9 p.m.

SIR ALNBROTH WRIGHT will deliver a lecture on the method of testing and judging the divers forms of wound treatment, at the Royal Society of Medicine, 1, Wimpole Street, W., on Wednesday, February 13th, at 5.30 p.m. The chair will be taken by the president, Sir Rickman J. Godlee, and the Director-General, A.M.S., Sir Alfred Keogh, G.C.B., intends to be present.

ONE of the main objects of the Central Association for the Care of the Mentally Defective is to give advice to parents and friends of individual defectives and to form throughout the country representative local voluntary associations to visit defectives in their own homes and advise the parents. It has arranged to hold a conference at the Guildhall, London, on Tuesday next, when the chair will be taken by Mr. Leslie Scott, K.C., M.P., at 10.15 a.m.

BREAD tickets came into force in Paris and its suburbs on January 23th. The system will be applied to the whole of France on March 1st. The ration is 300 grams (10½ oz.) a day. The reasons assigned for making this ration compulsory are two: first, the necessity of meeting the requirements for seed grain of farmers who are putting larger areas under wheat; and secondly, the demands on shipping caused by the transport of American troops to France.

MESSRS. H. K. LEWIS AND CO. ask us to state that all the copies of Binnie's *Regional Surgery*, vol. i, which had been announced for immediate publication, have been lost at sea through the wreck of the ship that was bringing them from America. Copies of Gould's *Pocket Medical Dictionary* and Stitt's *Tropical Diseases and Practical Bacteriology* were lost at the same time. The same publishers have nearly ready the sixth edition of Dr. H. Lewis Jones's *Medical Electricity*, revised and edited by Dr. L. W. Bathurst.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

MORBID FLUSHING.

AFFLUXUS asks for suggestions as to treatment in the case of a lady, aged about 45 years, with delicate skin and complexion, who has suffered since girlhood from an increasing intense flushing of the skin of the cheeks, temples, and neck, provoked by any deviation from the ordinary daily routine.

. This subject was discussed at some length in these columns a few years ago. The conclusion seemed to be that there is no specific that will cure this condition; it is a question of overcoming the reflex by practice. For the most part the treatment is a matter of auto-suggestion in which the assistance and encouragement of the medical man are important factors.

INCOME TAX.

A MEMBER is serving as captain in the R.A.M.C., and inquires as to the liability of his wife's income as matron of a military hospital.

. The joint income of husband and wife presumably exceeds £500, in which case separate abatement cannot be claimed, and the wife's pecuniary emoluments are liable to assessment. Our correspondent does not state the precise nature of his wife's appointment, but the special service rate—for example, 1s. 9d. in place of 2s. 6d.—applies if she is "paid out of money provided by Parliament," or is "serving in any work abroad of the British Red Cross Society, St. John Ambulance Association," or similar bodies.

"BEAT" HAND.

A CORRESPONDENT inquires whether there is any different procedure in the case of a miner and other industrial workers suffering from "beat" hand (cellulitis), and if so, what is the reason for the difference.

. The industrial diseases known as beat hand, beat elbow, beat knee are scheduled as such in the Workmen's Compensation Acts to apply solely to the occupation of mining. Consequently, only a miner, if suffering from these disorders, can apply to the certifying factory surgeon for a certificate of disablement, either employer or workman having the liberty of appeal through the registrar of the county court to a medical referee if dissatisfied with the certifying surgeon's certificate. Should the disorders arise in any other employment, the workman so disabled must establish, to the satisfaction of the county court judge, by the usual county court proceedings, that the condition followed personal injury by accident arising out of and in the course of the employment. The reason the simple procedure applies to mining is that beat hand, beat elbow, beat knee are considered specific to the employment of mining. If any trade can show that these disorders are so prevalent among the workmen as to be specific to that trade or employment, the matter should be brought to the notice of the Home Office for the purpose of having that trade or employment added to the schedule.

ANSWERS.

SPECIALIST PAY.

S. S. O.—In respect of their remuneration, officers in the army fall into two distinct classes. Class I receive what is known as consolidated pay, which covers the whole of their work, whatever it may be, and does not vary so long

as they are doing the work in question. Class II is remunerated partly by pay and partly by allowances. In the Army Medical Department one of the allowances is known as specialist pay. This can be obtained by an officer who makes a special study of certain subjects, passes the army examinations therein, and then succeeds in obtaining an appointment in which he devotes himself to the specialty in question. Surgery is one of those subjects and sanitation is another. The specialist pay was introduced for the purpose partly of encouraging army medical officers to continue to study professional subjects, but mainly in order to provide the army with its own specialists. It is not the obtaining of a certificate as a specialist that entitles an officer to specialist pay, but the obtaining of an appointment open to a specialist, which has been directly approved by the War Office through the officer in command of the locality or the division of the army concerned.

Temporary R.A.M.C. officers serving under contract would seem to fall into Class I. Their contract pay of 24s. a day, a higher rate than that drawn by lieutenants and captains (even when the allowances of the latter are included), is a composition rate, and covers the whole of their work. Nevertheless, the practice has arisen abroad of granting contract officers additional pay when they are holding specialist appointments in the same circumstances as would entitle regular officers to such pay, despite the fact that they have not "qualified" in such subjects after joining the army. Consequently, it might be worth while for our correspondent to make an application for specialist pay through the P.M.O. of his area.

LETTERS, NOTES, ETC.

CIVIL SURGEONS IN MILITARY HOSPITALS.

MALTA writes: Civil surgeons (Maltese) in military hospitals in Malta wear the ordinary officer's uniform, but with the St. John badge on the collar. They do not wear a Sam Browne belt.

MEAT, FISH, AND PEASE.

THE *Westminster Gazette* has found in a letter from Dr. Johnson to Mrs. Thrale the following statement, which may make some of us who are disposed to grumble at two meatless days blush: "Last week I saw meat but twice and I think fish once; the rest was pease."

EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

MISS ADELAIDE ROW is retiring from the post of Matron to the East London Hospital for Children, Shadwell, E. A number of those who have worked as residents or nurses at the hospital during the thirty-five years she has been connected with it have asked to have an opportunity of expressing their regard for her, and the exceptional success of her administration, but there are doubtless many others who would like to contribute to the testimonial which it has been decided to raise. Subscriptions will be acknowledged by Mr. W. M. Wilcox, secretary, at the hospital.

THE CAUSATION OF SEX IN MAN.

W. E. L. writes: With reference to the note by Dr. J. Singleton Darling, M.D., in the *JOURNAL* of January 26th, p. 135, I should like to know if Dr. Darling is absolutely certain beyond all possible doubt that not even a particle of the left ovary was left in the broad ligament. I have proved Dr. Rumley Dawson's theory correct in 81 out of 87 cases.

THE BASLE ANATOMICAL NOMENCLATURE (B.N.A.).

B.A.OXON. writes: For the last four or five years the Basle anatomical terminology has been finding increasing favour amongst students of anatomy, but now a reaction in favour of the old terminology appears to be setting in. It is not my intention to enter into a discussion on the relative merits of the two terminologies, but perhaps I may be excused if I quote a brief extract from Professor Arthur Robinson's preface to the fourth edition of *Cunningham's Anatomy*. He says (writing in April, 1913): "It is scarcely necessary, to-day, to urge reasons for the use of the Basle nomenclature, for it is now generally recognized, not only that it is based on sound general principles, but also that it is, at the same time, less cumbersome and more definitely instructive than the terminology previously in use in this country." Surely it is time that the profession decided which terminology is to be taught in the various medical schools in the United Kingdom. The situation at present is impossible. All the latest editions of the textbooks contain the new terminology, and yet the vast majority of teachers of anatomy continue to use the old. The result is that the unfortunate student has to learn both—an unnecessary tax upon his already overburdened memory, especially at a time when he is urged to qualify in the least possible time.

*. The views of those teachers of anatomy in this country who are indisposed to countenance the anatomical nomenclature adopted by the German Anatomical Society at its meeting in Basle in 1895 were fully stated by Professor Arthur Keith in the *BRITISH MEDICAL JOURNAL* on July 28th, 1917, p. 134, and in that issue an editorial article on the subject was published (p. 121).

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND. The following subscriptions to the Fund have been received during the week ending Monday, January 28th:

	£	s.	d.		£	s.	d.
Lient.-Col. J. G. Adami,				Sir Thomas Barclay ...	20	0	0
A.D.M.S. ...	2	2	0	"Clandius Civilis" ...	6	0	0
Dr. J. Tremlett Wills ...	5	5	0	Mr. Walter Hills ...	5	3	0
Jersey Medical Society				Dr. J. H. W. Laing ...	1	1	0
(per Dr. O. C. Powell)	2	2	0	Major Charlesworth ...	2	2	0
Dr. Florence Stonay ...	2	2	0	Dr. J. Auriol Armitage...	5	5	0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE STERILIZING OF HYPODERMIC SYRINGES.

DR. C. D. SOMERS (Aldeburgh) writes: In selecting the best method for sterilizing syringes, it has to be remembered that besides sterilizing the syringe one has to remove all traces of the sterilizing solution in case it affected the serum that is about to be used. The quickest and best way is to place the syringe into methylated spirit and then burn it off, or else to boil the syringe in methylated spirit, but for this a sand bath is necessary and is not applicable for the bedside. Now that it is so difficult to obtain methylated spirit I should be most grateful if I could discover some solution that is safe and quick in action; but, for reasons stated above, I should be afraid to use the solution recommended by Dr. Lyon Smith, not that any harm would be done, but in the case of vaccines the desired effect would not be obtained.

AN ERRANT FISHBONE.

DR. I. DAVID (Colombo) writes: The following notes on a case of a fishbone accidentally swallowed and said to have been expelled per urethram after two years and five months were read before the Ceylon Branch of the British Medical Association on November 19th, 1917: A respectable, intelligent patient of mine, aged 40, of Jewish descent, consulted me on April 30th, 1915, because he had accidentally swallowed a fishbone while eating his dinner. As he showed no serious symptoms which called for interference, I advised him to leave it alone; but without consulting me he took a strong purgative the next day. On May 2nd, three days after the accident, I was sent for again. On arrival I found him suffering from a severe pain in the back and lower abdomen, most intense in the region of the bladder. The urine passed was muddy and mixed with blood, and his temperature was 102° F. I diagnosed the case as acute cystitis, and put him on the usual treatment. He got over the attack in about two weeks. He had a second attack of cystitis on September 9th, 1916, and a third attack on April 9th, 1917, which lasted for one month, and a fourth attack on September 5th, 1917. During each attack he suffered severely from difficult and painful micturition. On September 15th, while having a hot hip bath, he found it extremely difficult and painful to micturate, but by straining and massaging the perineum with the fingers, a fishbone (triangular in shape, $\frac{1}{2}$ in. by $\frac{1}{2}$ in., thin and sharp-edged) is said to have appeared at the external urethral meatus with free bleeding. The bone presented with its apex foremost with its body folded lengthwise. The patient was able to extract it for himself. I was sent for at once and shown the bone. I have not the slightest reason to doubt the statements made to me by my patient, whom I had known for more than seven years. Evidently the fishbone entered the bladder on May 2nd, 1915, from the rectum through the space intervening between the peritoneal fold and the prostate, or by some other route, and remained in the bladder for twenty-nine months, until expelled as described above.

U.S.A. MEDICAL CORPS.

A NEW section of the office of the Surgeon-General of the United States army has been established charged with the duty of providing moving pictures or slides of camp activities relating to the work of the medical department. The films and slides are to be available for purposes of instruction in medical schools, officers' training camps, and the National Guard and National Army camps.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under ...	0	6	0
Each additional line ...	0	0	9
Whole single column ...	4	0	0
Whole page ...	12	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

POSSIBLE PITFALLS IN LIFE ASSURANCE EXAMINATION,

AND REMARKS ON MALINGERING.*

BY

F. PARKES WEBER, M.A., M.D., F.R.C.P. Lond.

In thanking the society for electing me its President, I feel that it must be a difficult task for me to occupy worthily a post which has been in turn held by my father, by one of my distinguished masters at St. Bartholomew's Hospital, and by several others whom I admire and honour.

EXAMPLES OF DISEASE WHICH MAY ESCAPE DETECTION AT LIFE ASSURANCE EXAMINATIONS.

Arterial Hypertension, with or without Granular Kidneys.

—It is certainly quite easy at a single examination to overlook a case of hypertension if one does not employ the sphygmomanometer, even when the brachial systolic blood pressure is as high as 190 or 200 mm. Hg. Here we have the grave risk of premature death from such causes as cerebral haemorrhage, etc. In many cases the urine may be found on repeated testings to be free from albumin, and tube casts may be absent, or only one or two hyaline casts may be discovered by the help of the centrifugal machine, as they may be sometimes in the urine of healthy persons. Ophthalmoscopic examination may likewise show nothing abnormal in this class of cases. The heart may not appear enlarged by ordinary examination, notably in fat or fleshy subjects; moreover, a moderate amount of pulmonary emphysema may mask hypertrophy of the left ventricle.

Disease of the Myocardium or Coronary Arteries of the Heart in Syphilitic Subjects.—In early cases, without knowing the subjective symptoms, one may easily overlook disease of this nature at a life assurance examination. Moreover, a history of past syphilis may not be forthcoming. The Wassermann reaction is not likely to be taken. A first attack of angina pectoris may be fatal. Other grave symptoms of myocardial disease may suddenly develop in young or middle-aged individuals. Sometimes considerable areas of the cardiac wall undergo degenerative changes owing to obstruction in their supply of arterial blood, and then death is likely to occur rather suddenly before a true cardiac aneurysm has developed.

Malignant tumours in the thorax or abdomen may easily be overlooked in an early stage of their development, especially at a single examination. Symptoms regarded as connected with ordinary dyspepsia may signify commencing cancer of the stomach. In some cases the persistent absence of free hydrochloric acid in the contents of the stomach after a test breakfast might have furnished valuable evidence as to the nature of the case, though it must be admitted that free hydrochloric acid is probably more often absent in non-malignant conditions than is ordinarily supposed. It is not surprising that an operation for a malignant tumour in the abdominal viscera may occasionally be heard of in bona fide cases not long after acceptance for life assurance, even when there was no suggestion of a tumour being present at the time of the life assurance examination.

Disease of the suprarenal glands, notably primary malignant disease (malignant hypernephroma), may escape recognition at first. Tuberculous disease, with caseous degeneration, in one or both glands, is often not recognized, even if there are asthenic symptoms, before the characteristic cutaneous pigmentation of Addison's disease has developed. The following case bears on the question of the difficulty in the diagnosis of "latent Addison's disease," with asthenic symptoms and delayed recovery from infections, before the typical cutaneous pigmentation has developed.

In December, 1899, I saw a man, aged 24, suffering from a pyrexial attack, which was regarded as influenza. The illness was accompanied by some pleurisy at the left base, and was followed by remarkable debility. Several medical consultations were held, and gradually he apparently recovered. In 1901, when shooting in India, he was attacked by malaria, probably not a particularly severe attack, and was sent up to the hill station of Darjeeling. There his condition was one of great

asthenia without fever, and he had syncopal attacks, in one of which he died. Some pigmentation was observed in India, though none had been noted during the illness in England. A most careful *post-mortem* examination was made, and in a report sent over to a life assurance office in England it was stated that the suprarenal glands contained yellow caseous material and calcareous plates, and were matted together across the aorta. It seems to me that suprarenal disease (latent Addison's disease) was probably the true explanation of the asthenic condition connected with convalescence from the previous illness in England, and was perhaps also present when his life was heavily assured at ordinary rates by a great English life assurance company before the illness in question. More than one English company was affected by his early death.

Cirrhosis of the liver is sometimes very hard to detect, especially in fat or apparently well-nourished persons, with thick abdominal walls which make palpation of the liver or spleen difficult. In such cases the disease, though it may have had an ordinary alcoholic origin, may be not only quiescent, but also actually latent. When the abdominal walls are thin or flabby, the hardened liver generally seems enlarged to palpation, even when it is in reality more or less atrophic. Evidently the position of the liver is changed in such cases, for the lower margin can usually be felt projecting below the costal margin. Slight enlargement of the spleen can often likewise be made out, and this, together with an occasional subicterio tinge of the conjunctivae, and perhaps (when present) relatively dark-coloured urine, and excess of urobilin in the urine, may facilitate the diagnosis.

Splenic Enlargement.—Every medical examiner knows the difficulty in regard to slight chronic enlargement of the spleen, when the enlargement is not certainly the result of malaria. I suppose no candidate for life assurance with great enlargement of the spleen would be accepted, whatever the nature of the enlargement might be. I may draw attention here to a certain rare class of cases of splenomegaly. A young woman, or a young man, suddenly complains of considerable pain in the upper part of the abdomen, possibly accompanied by temporary fever and a little ascites. The ascites soon disappears, but the spleen is found to be enlarged, and there is probably slight anaemia. Soon the pain passes off, the patient feels well, and there may be no anaemia, but more or less enlargement of the spleen persists. In some cases there may be a little early haematemesis. Later on the patient may seem and feel as well as any healthy person, in spite of the persistence of the splenomegaly. After a year or two the blood count will probably show nothing abnormal excepting moderate leucopenia. For the clinical aspect of the case at this stage I have suggested the term "anaemia splenica sine anaemia." Sooner or later, however, grave haematemesis is likely to occur, and the case will then probably be diagnosed as one of splenic anaemia or Banti's disease. But in this class of case, as *post-mortem* examination shows, the real cause of the splenic enlargement, haematemesis, etc., is a kind of pylophlebitis adhaesiva, with resulting obstruction in the splenic and portal veins.† The obstruction to the return of blood from the spleen may become compensated, and the disease may remain quiescent for a long period, but fresh attacks of thrombosis in the portal vein are apt to occur, ultimately leading to complete obstruction. There may or may not be a history of traumatism at the commencement of the disease, and the etiology of the thrombo-phlebitis in these cases has not been satisfactorily explained.

Pulmonary Tuberculosis.—I need scarcely mention the well-known danger at single life assurance examinations of failing to recognize the presence of early pulmonary tuberculosis, especially when, for one reason or another, the medical examination is somewhat hasty or incomplete. Early cases are by no means always the most favourable cases of pulmonary tuberculosis. Apart from the general nutrition and build (and possibly the family history) there are no data at first to help one to form an opinion as to how the disease is likely to progress or how efficient ordinary hygienic and therapeutic measures are likely to prove to be. On the other hand, in old cases, and after the disease has been under observation for a considerable time, the resistance of the patient has been more or less estimated. When a person is not overwhelmed by the disease, even when it has considerably progressed, the power of gradually acquired resistance and compensation

* Presidential address before the Assurance Medical Society, January 9th, 1918.

† For one of many typical examples of this kind of case see F. Parkes Weber, *Proc. Roy. Soc. Med., Clinical Section*, 1916, vol. ix, pp. 1-6 (including the discussion which followed the paper).

may prove to be tremendous. A man may be slowly "chased through life" by the disease and yet live to a fair, or even old, age. The disease, although very advanced and after extensive cavernous formation has taken place, may ultimately become quite quiescent or obsolete, and death may occur from other causes.

In September, 1909, I saw a gentleman (W. M. M.) with extensive cavernous signs over the upper part of the left lung, back and front. He was 67 years old, but looked rather younger. Cavity formation had occurred, according to the history, in the upper part of the left lung after an attack of measles at the age of 16 years. At 38 years of age he is said to have had a bad "cold" so that "the hole in his left lung got disturbed," and the pulmonary tuberculosis became active again. Since that time he had been much abroad, in Egypt, Malta, the West Indies, and Madeira, but especially in the Canary Islands. For some time he had had a house near Las Palmas in Grand Canary. A tragical complication for the patient was the death of his wife (to whose devoted attention he owed so much) by suicide, a few months before I saw him, in 1909. He died at Pau in January, 1913, aged 70.

Diabetes Mellitus.—When diabetics are passed in life assurance examinations the most probable reason is neglect or mistake in urine examination, but it must not be forgotten that by means of the modern fasting treatment the urine can often be rendered temporarily free from sugar in the case of young patients (often apparently well nourished), precisely those who are almost certain to die early from diabetic coma. Such cases would, I believe, often be passed, if fraudulently sent up for life assurance examination after a preparatory course of fasting treatment. In 1909, before the general introduction of the treatment of diabetes mellitus by Allen's fasting method ("alimentary rest"), the urine in a grave case under my care was temporarily freed from sugar in the following way:¹

The patient was a young woman, aged 23 years, an in-patient at the hospital. The sugar in the urine was reduced by dieting to about 70 grams for the twenty-four hours. On September 10th, 1909, the diet was temporarily limited to 200 to 300 grams of olive oil in the day, with as much water as was wished, and a codein-phosphate pill (which the patient had been taking three times a day) was continued. As a result of this "disguised starvation" method sugar completely disappeared from the urine on September 12th. On September 13th I ordered a return to the special diet which she had previously been having for her diabetes, and on the next day the urine was found to contain 4.5 per cent. of sugar. During the days of exclusive olive oil diet the patient did not feel hungry or as if she was being starved. Once or twice the oil, she stated, made her feel a little sick, but she looked well and had her usual, somewhat florid, complexion. She lost only about 4 lb. in body-weight. She was not emaciated, and, on the whole, gained weight whilst she was in the hospital.

This case was certainly one of grave diabetes mellitus, and afterwards died, as I heard, from diabetic coma, but surely a life assurance examiner, had he examined her when the sugar disappeared, might have been deceived.

Syphilis and So-called Parasyphilis of the Nervous System.—Nervous syphilis is supposed by some to have become relatively more frequent since the introduction of the methods of treatment by salvarsan and neo-salvarsan. The blood serum and cerebro-spinal fluid are naturally very seldom (if ever) tested, regarding the Wassermann reaction, for purposes of life assurance, and it is quite possible that persons actually suffering from headache, etc., connected with commencing nervous syphilis, may occasionally be accepted for life assurance. Future statistics of the great life assurance companies as to the causes of death in early claims will doubtless throw some light on these questions. Similarly, persons with commencing tabes dorsalis or general paralysis must sometimes be unwittingly accepted for life assurance—especially if no history of previous syphilis is forthcoming. I doubt whether as yet Argyll Robertson pupils are sufficiently examined for and the knee-jerks tested as a routine part of life assurance examinations. But occasionally at (several) repeated examinations knee-jerks cannot be elicited in neurasthenic, and even apparently quite healthy, individuals. One must acknowledge that tabetic symptoms, such as tabetic pains, tabetic paraesthesiae, gastric crises, and tabetic urinary troubles, are frequently supposed to be due to other causes. It may be noted, however, that patients with tabes dorsalis often live a long time, and in some cases the life assurance companies would not be losers if tabetics were accepted by mistake. Tabetics in whom optic nerve atrophy occurs early seem often to have

a relatively mild form of the disease in other respects—so much so that, I believe, in France, about Charcot's time, a kind of "arrested tabes dorsalis with blindness" was spoken of—that is to say, a class of tabetics was recognized whose symptoms (that is, the progress of their disease) were arrested by (or, rather, after) the development of optic nerve atrophy.

MALINGERING.

Knowledge in regard to the simulation of symptoms and diseases is of extreme importance for workmen's and accident assurance. The combination of simulated with genuine signs or symptoms is often especially difficult to detect. Functional nervous diseases and simulation of organic diseases are not rarely associated with each other. The artificial skin affections which I have seen have been chiefly in young women with abnormal psychical states. Unfortunately in these cases, as in other cases of artificially produced disease, though the artificiality of the disease may often be recognized, the exact means whereby the condition is produced frequently escapes detection.

Most of us recently have had to pay attention to the question of various forms of simulation in men. Amongst prisoners of war simulation of disease for purposes of repatriation tends of course to be regarded as fair play, and as rather creditable than discreditable, if it is successful. In such persons, however, as in accident insurance cases and "traumatic neurasthenia," there may be a real functional nervous element combined with the simulation of disease. In some cases a functional nervous disease may constitute the chief trouble, not combined with actual simulation, but fostered by a desire not to recover until liberty is regained, just as ordinary traumatic neurasthenia may be kept up and fostered by a desire to obtain monetary compensation, etc.

An intelligent and highly skilled business man, aged 36 years, had right hemiparesis and what seemed to be a kind of myoclonus (paramyoclonus) multiplex. He could not speak, except in a whisper, and could not walk. He was allowed by the military authorities to return to his native land, and I afterwards heard that not long after his return sudden recovery of speech and power of walking followed the shock of a fall from a tram-car.

This reminds me of some remarks in a recent paper by E. Farquhar Buzzard,² in the course of which the author stated that he mistrusted the complete genuineness of many of the reported sudden recoveries from functional nervous disorders (including functional loss of speech, etc.) following—that is, as result of—shocks. He suspected that the patients began to be tired of their loss of speech, etc., and began to be sure that their trouble was no longer really necessary; he thought that they then gladly accepted some "shock" or other exciting circumstance as a kind of "excuse" to recover suddenly. I wish some beneficial "shock" had occurred in an aggravated case of "chorea rhythmia" (functional) which was under my care for a long time.³

The patient was a man, aged 38 years, of Hebrew origin. When he was being examined by a doctor, the rhythmic movements of the neck and arms used to become increased in rate and amplitude and force. They quieted down somewhat when he was left to himself, and ceased altogether during sleep. They became more violent when any one tried to restrain them by force in any way. He said he could not walk, but he was able to move his lower extremities when he was sitting or lying down. He gave one to understand that he could speak only in a very slow and jerky manner, as if battling against some obstruction in articulation. On the other hand, he could eat, drink, and dress himself fairly well, when left alone, without any assistance. He was at first not losing weight, but afterwards he lost slightly. He was apparently free from any visceral disease. His knee-jerks were exaggerated; no ankle clonus could be obtained; his plantar reflexes were difficult to obtain, but, when obtained at all, they were of the flexor type. Obviously psychical factors played an important part in the case. The patient was removed to another hospital and I lost sight of him, but perhaps he has been allowed to regain his liberty, and in that case rapid improvement may have taken place.

In some cases I believe it is very difficult to distinguish between what one might call *bona fide* functional paresis (with limping on one lower extremity) and actual simulation, and equally difficult is it to distinguish between genuine painful remnants of sciatica and simulation.

A remarkable case of simulated amblyopia was complicated by a temporary attack of genuine optic neuritis. An intelligent man, aged about 45 years, with special

knowledge of chemistry, was repeatedly examined by two ophthalmic experts, and there can be no doubt whatever that typical optic neuritis was actually present for a time; it could not have been simulated. He, however, apparently managed, for purposes of simulation, to have his pupils generally under the influence of atropine, but occasionally, when examined unexpectedly, his pupils were found to react to light. On an occasion, later on, when he met one of the eye doctors unexpectedly, he committed the involuntary mistake of addressing the doctor, before the latter had spoken or given the patient any opportunity of recognizing him, except by sight. As to the possible causes of the attack of true optic neuritis in this case it may be remarked that the patient's blood serum gave a positive Wassermann reaction, that he complained of (possibly genuine) headaches, that he was given anti-syphilitic treatment, and that the Wassermann reaction afterwards became negative. One day the specific gravity of this patient's urine was found to be 1057, which I think was probably due to some common table salt having been emptied into it. It is quite possible that the patient had noticed that on ordinary urinometers used in England the portion of the scale above 1030 is marked "diabetes" on the reverse side. Owing to this curious statement, perpetuated on nearly all these instruments, as used by doctors and in hospitals, the idea may suddenly have occurred to him that by artificially raising the specific gravity of his urine he might simulate an important symptom of diabetes mellitus. If so, he probably gave up the idea when he found that, owing to the absence of sugar from his urine, the disease in question could at once be excluded.

TWO YEARS' EXPERIENCE OF SEPTIC WOUNDS IN A V.A.D. HOSPITAL.

BY

ALEXANDER BLAIR, M.D.,

MEDICAL OFFICER, DUNCOMBE PARK V.A.D. HOSPITAL, YORKSHIRE.

WHILST it is true that many of the cases seen at a V.A.D. hospital are obviously selected as suitable for removal from the parent hospital, and that a certain number are already well on the way to convalescence, some at least are sufficiently serious to demand considerable care and constant attention. The great majority of the wounds are septic, and some of them have been treated at the military hospital with indifferent success, and are sent to the auxiliary hospital in the hope that an improvement in the environment may make for recovery. Many of the wounds are very foul, especially those of the limbs, and are suppurating freely. A certain number have been operated upon for the removal of bullets, fragments of shell, and pieces of necrosed bone. Sometimes recent cases are sent, and men have been admitted to Duncombe Park within a few days of being wounded and still dazed from the shock of battle. Our most intractable cases have been those in which the lower limb was involved, with sepsis arising from an infection of bone. Wounds in or about a joint are also, as a rule, serious.

From the outset our aim has been to treat wounds conservatively, with as little operative interference as possible, taking the view that the hospital partakes largely of the nature of a convalescent home. The patients are given a generous diet, and kept in the open air as much as possible. The hospital stands in most beautiful surroundings in a wide, open park overlooking the Yorkshire moors, and sheltered from the north and east. Suitable recreations and amusements, both outdoor and indoor, are provided, and a continuous atmosphere of cheerfulness is considered an integral part of the treatment.

Where there is obviously a foreign body in a wound, whether it be part of a projectile or a sequestrum of bone, the irritant is removed and drainage established at the earliest moment. One of the first operations was for a piece of shell at the bottom of a discharging sinus in a soldier who had been treated for tetanus in France. The

precaution was taken to give an injection of antitetanic serum, a procedure which since then has been widely recommended. Sometimes it has been necessary to reopen a wound to a considerable extent, or even to amputate, where the flaps were too meagre to cover a bad stump. Exposure to direct sunlight, in almost all cases, has been followed by good results, and bad cases have done best when removed from the wards and housed in shelters in the grounds. Our experience leads us to place reliance upon outdoor treatment with the minimum of dressings. Cases which at first appear almost hopeless begin to show healthy granulations in a very short time, and the patients soon become able to move about without assistance. A trained masseuse has done excellent work in the after-treatment of wounds where there is stiffness or contractions; when healing is delayed and there is no foreign body in the wound, massage is a means of speeding up the healing process.

With regard to antiseptics, at first there was comparatively little to choose between the antiseptics available. A solution of carbolic acid, lysol, or mercury biniodide, or a light dressing saturated with hypertonic salt solution, was employed with success in the milder superficial wounds. Wet dressings were discarded as far as possible, and the source of the suppuration searched for and removed. Deep-seated wounds, especially those of the lower limb, with infection of bone, and a foul sinus leading down to the damaged tissues, gave greater trouble, and it was soon discovered that the "physiological" method advocated by Sir Almoth Wright often failed to produce healthy granulations. Any endeavour to open up the wound, with a view to removing the infective irritant, usually necrosed bone or a piece of shell or casing of bullet, was apt to cause a septic invasion of the subjacent healthy tissue, and extensive osteomyelitis developed on at least one occasion. The ideal procedure of cleansing the wound thoroughly at one sitting, and afterwards applying dry dressing, was found impracticable and had to be abandoned. Where there was great sloughing of the parts the damaged tissue that could be reached without much cutting was removed, a stream of warm hydrogen peroxide introduced into every part of the wound and suitable drainage established. Where the suppuration was very profuse and there was swelling and redness of the parts, hot boric fomentations frequently applied gave good results, and where there was a compound fracture also, the continuous antiseptic bath was found to be the best treatment. Extensive frostbite and bad cases of trench foot also did well when treated in the bath. Foul sinuses of long standing, with thick ropy pus, were treated, according to the teaching of Lister, with pure carbolic acid, then irrigated with hydrogen peroxide in a gentle stream, and lightly covered with gauze and exposed to sunlight. An endeavour was always made to explore thoroughly all pockets in the wound; one of these overlooked was often the cause of delayed healing. Ensol and the Dakin-Daufresne solution have been more lately employed and are useful, as is also the introduction of the bipp paste of Rutherford Morison, the advantage of the latter being the lessened frequency of disturbance of the wound. For a time the mixture of ichthylol and glycerin was used with fair success. Each of these methods has its advantages as well as its disadvantages. We have not yet had the opportunity of testing flavine¹ and brilliant green. Meantime, our experience points to the superlative importance of sufficient drainage; given that, the antiseptic employed is of secondary importance. With faulty drainage, or a septic body deeply lodged in any part of a wound, the most ideal antiseptic will fail to produce healthy granulations and a sound cicatrix. Hence it is that different surgeons produce favourable results with widely varying substances which have been demonstrated to be anything but good antiseptics.

The following case goes to prove that drainage is the most important element in the treatment of a foul wound:

Sgt. B., admitted to Duncombe Park Hospital on June 14th, 1916, suffering from a deep suppurating wound of the right groin. He had been under treatment for nearly five months. The wound was opened up freely and swabbed out with pure carbolic acid and then daily irrigated with a warm solution of hydrogen peroxide. A long drainage tube was inserted reaching to the bottom of the wound. A pocket at right angles to the sinus was subsequently discovered and freely cleaned out and a packing of iodoform gauze inserted. The patient was removed to a shelter in the grounds and the

wound daily exposed to the sun; it healed soundly, and the patient was sent back on July 8th. A year later there was no recurrence.

The objection to rubber drainage tubes, quoted by Surgeon-General Sir George Makins,² has not been upheld by our experience, though it is probable that Rutherford Morison's system is now in use in many cases in which the rubber tube was formerly employed for the purpose of drainage.

After an experience of more than two years in a V.A.D. hospital I feel impelled to state that I have not yet met with anything materially different, as regards sepsis in wounds, from what I find in my own practice in this wild agricultural district. I am constantly seeing wounds that have been neglected for more or less prolonged periods, or treated by ignorant villagers with various abominations. These wounds are frequently fouled with earth and manure and greatly resemble the cases admitted to the hospital. It seems to me to be purely a matter of degree, with the absence in civil practice of the great depression and shock so often seen in the soldier. The treatment is much upon similar lines.

The importance of rest is great; placing the injured part in a position of immobility, with free access for dressing, where there is loss of bone in the lower limb, was found the best method of treatment. Where there is delayed healing due to persistent sepsis along the planes of fascia, and there is no necrosed bone or other foreign body, complete immobility may make the difference between success and failure. Many wounds seem to remain open, with weak, flabby granulations, especially where there has been extensive loss of tissue in the neighbourhood of the femur or the tibia. The wound heals up to a point and then remains obstinately open. Elastic pressure, as recommended by Liek,³ has given good results in such cases. Plenty of padding should be employed, and there should be a fair amount of pressure. The circulation of the limb is usually disturbed in these cases of delayed healing, giving rise to one or more ulcers with depressed bases and undermined edges. In a neighbouring V.A.D. hospital radiant heat has been the most successful means of treating these wounds, but has not been in operation at this hospital.

Dealing with a class of wound often in the condition of chronic suppuration, surely the most unpromising for any kind of treatment, as it is engrafted upon a constitution debilitated by exposure and prolonged fatigue, it is pertinent to inquire the proportion of failures to successes in treatment. I can recollect only one case that was not greatly benefited after prolonged treatment. It was one in which practically the whole femur was involved. For a time he did fairly well and the wound almost ceased to discharge. Then in an evil moment I operated for an extensive sloughing of the tendo Achillis, caused by pressure from a faulty splint applied abroad, I believe. There was extensive spread of the sepsis along the limb with osteomyelitis of the femur, and the limb had to be amputated. In chronic cases it is advisable, in my opinion, to give the limb a fair chance before resorting to extreme measures, and in a great proportion of such cases conservatism is fully justified. There is less likelihood of the surgeon being placed in a dilemma in a V.A.D. hospital than in a large hospital where the cases dealt with are of recent origin. In a small V.A.D. hospital of 30 beds, staffed chiefly by Red Cross nurses, the opportunities for observation as well as treatment must remain strictly limited.

Conclusions.

1. Treatment in a V.A.D. hospital should be, generally speaking, upon conservative lines.

2. Complications should be looked for and the cases carefully watched, and operations avoided unless distinctly indicated.

3. If the source of suppuration is of easy access, it should be removed early.

4. In deep-seated sepsis it is better to operate after antiseptics have been given a fair trial than to permit the case to drift into a condition of long-continued suppuration.

5. Where a wound is improving, even if slowly, patience should be exercised, rather than risk a septic invasion of the surrounding healthy parts by a cutting operation.

6. All classes of septic wounds are benefited greatly by outdoor treatment; the sun bath is a potent means of inducing healthy reaction in most cases.

7. It should be recognized that V.A.D. hospitals have their limitations, and that rest, good food, fresh air, and a cheerful outlook are the factors which are of most value in the treatment afforded by them.

SUMMARY.

Cases admitted to Duncombe Park V.A.D. Hospital, from June 28th 1915, to June 28th, 1917.

THE TECHNIQUE OF THE CARREL-DAKIN TREATMENT.

BY

CAPTAIN G. E. MCCARTNEY, C.A.M.C.,

AND

CAPTAIN F. H. H. MEWBURN, C.A.M.C.

In the following description of the method used in the Carrel-Dakin Ward, which has been in operation at the Duchess of Connaught Canadian Red Cross Hospital, Taplow, for fifteen months, standard methods are, as much as possible, passed over, and those details which have been introduced during the last year especially described.

The solution is prepared daily in the dispensary according to the method of Dr. Daufresne,* tested for hypochlorite content, and sent to the ward in a carboy of amber glass, without the addition of the potassium permanganate. The solution is at once tested by one of the surgeons, and if found of correct strength, the potassium permanganate is added and the bottle stored in a closet until used.

A study of the wounds treated with solutions of different strengths of hypochlorite has convinced us that the upper limit of strength of Dakin solution should be reduced. The use of the solution around 0.5 per cent. often causes

* The Dakin solution is prepared according to the technique of Dr. Daufresne as set forth in the circular of the laboratories of the Rockefeller Institute at Compiègne (Mission of Dr. Carrel), dated December 15th, 1917. The amount of potassium permanganate used to stabilize the hypochlorite is 5 mg. to each litre of Dakin's solution.

the wounds to develop a scalded, white appearance not seen with the lower strengths. We have endeavoured to limit our Dakin solution to between 0.460 per cent. and 0.485 per cent., between which percentages we consider we obtain the best results.

All the Dakin bottles in the ward are fitted with a rubber cork, rubber tubing, and pinch-cock. This was found to be more satisfactory than closing the mouths of the bottles with cotton-wool. Pinch-cocks on both stopper and irrigating tube are opened when the solution is being used.

A series of tests was conducted to determine the action of light on the solution in different types of protected bottles. The tests were made with Dakin solution in bottles exposed to winter light on a verandah. More marked results would be expected in the brighter light of summer. The first bottle was uncoloured glass, the second was thoroughly shellacked with Bismarck brown (amber-coloured glass bottles being unobtainable), whilst the third was enclosed in a bag of heavy duck impregnated with a brown floor stain.

On beginning the test—

The strength of the solution was hypochlorite 0.499150 %

At the expiration of 24 hours—

Uncoloured glass bottle showed hypochlorite...	0.406125 %
Bismarck brown bottle " " "	0.473075 %
Duck covered bottle " " "	0.487975 %

At the expiration of 48 hours—

Uncoloured glass bottle showed hypochlorite...	0.379950 %
Bismarck brown bottle " " "	0.461900 %
Duck covered bottle " " "	0.473075 %

These figures prove (a) that the brown duck covered bottle is the best for the protection of the solution, and (b) that, properly protected, the solution will retain its potency for at least forty-eight hours. Hence we use only the brown duck protected bottles.

A well-equipped dressing carriage is essential. A liberal supply of instruments, including eighteen pairs of thumb forceps, several pairs of scissors and sinus forceps, is needed. We use several syringes with rubber tubing and nozzle attachment to avoid any hand contact with wounds, also a separate container with long forceps for the use of the nursing sister, all instruments being sterilized after use by ten minutes' boiling.

We consider the disinfection of the Carrel tubes and the preparation of the vaseline pads most important. The Carrel tubes, after use, are syringed out with warm water, scrubbed with a brush, soaked all night in Dakin solution, washed off with ether, and then boiled for thirty minutes in a caustic soda solution.

In the preparation of the vaseline pads, ordinary dressing gauze with eight or ten threads to the inch is entirely unsuitable, as it does not retain sufficient vaseline. Cheese cloth, with twenty-four threads to the inch, gives the best results. This is cut in strips 6 in. by 4 in., one end turned up, and, in sets of twenty, dipped into hot vaseline. The surplus vaseline is drained off and the strips are placed neatly in layers, in a tin box with a perforated lid. This is repeated until the box is full, when the box is pinned up in a towel, and sterilized in the operating room. The resulting pads are thoroughly impregnated and adhere perfectly to the skin, allowing no Dakin solution to penetrate.

In the Dakin service at this hospital the medical officer invariably does all the dressings. This rule is rigidly enforced, as in no other way can there be certainty of the technique. It is possible for one medical officer to dress fifty cases a day, but it is difficult where his work also includes operations and clerical work. We have hence found two medical officers necessary for such a ward. As assistants we have one nursing sister (well trained), and two orderlies, one of whom may be an intelligent convalescent patient. Both nursing sister and head orderly are fixtures in the ward, as satisfactory team work and thorough asepsis are only obtained by permanent assistants. Their duties include no ordinary ward work, and are limited to the dressings and preparation of the same. One orderly looks after the sterilization and delivery of successive instruments; the other assists with the patients and on the carriage. The sister's attention is restricted to the carriage, handling all instruments and dressings by long forceps. In handing the medical officer the various instruments, tubes, and dressings, the sister's forceps are not allowed to touch those used by the surgeon.

The essential point of the dressing technique is that the wounds, tubes, and dressings, are on no account touched by the hands. Everything is handled solely by clean dressing forceps. No patient who is to be dressed should have Dakin solution less than two hours before the dressing. This ensures that the bacterial count is not diluted. After the old dressings are removed, a smear of the wound is taken on a clean glass slide, on which is marked the patient's name and the date. The slides are collected, and taken to the pathological laboratory, where the bacterial count is made and entered in a book, from which entries may be made on the patient's case sheets. Wounds are syringed with normal saline or Dakin solution. The surrounding skin surfaces are then carefully dried. One ply of the vaseline pads is next applied accurately to the edges of the wound and well smeared to the skin. It is most important that these pads should have sufficient vaseline so that they may adhere firmly. This allows any overflow of Dakin solution to pass over the vaseline and be absorbed by the large pads. If not, the Dakin solution passes under the pads and a most obstinate "Dakin dermatitis" results. These vaseline pads should be applied to a greater depth from the dependent sides of the wound. Carrel tubes are next applied. Surface wounds may be covered with a single layer of gauze, which may be kept in place by making it adhere to the vaseline pads surrounding the wound. A large pad of suitable size, made of absorbent cotton covered with gauze, is then applied. The idea of this pad is not to cover the wound, but to soak up any discharge which may result from the treatment. It has been our experience that wounds do much better when not completely shut off from the air. In the case of a wound on the anterior surface of the leg, this pad would be applied around the under side and pinned at each end, leaving the wound uncovered by the large pad. Forceps are changed after the old dressings are removed, and the Carrel tubes should be handled by clean forceps.

One of the hardest things is to keep the tubes in position in a large flesh wound. This can be made easier by employing specially shaped tubes. For long flesh wounds we employ a tube tied an inch or two from the end; holes are punched in it corresponding to the length of the wound. It is kept in place by strips of adhesive tape at each end of the wound. Rings of various sizes are useful not only for encircling the ends of stumps, but often are much easier to keep in position on flesh wounds. The object of placing Carrel tubes in a wound is to ensure that the flow of Dakin solution will cover the entire surface. The position of the patient at the time of dressing must be taken into account, as it may not be that which he usually occupies.

Conclusions.

We wish to emphasize the following points in the operation of a Carrel-Dakin ward:

1. All Dakin solution should be tested personally by the surgeon before use.
2. The upper limit of hypochlorite is best at 0.485 per cent.
3. Brown duck bags give the best protection to the solution.
4. Well-equipped dressing carriage and good team work are essential.
5. Vaseline pads properly made and properly applied give the best protection against "Dakin dermatitis."
6. Absolute "joint" asepsis in dressings is essential.

The results obtained with this technique have been most satisfactory in the majority of cases. The asepsis has to be rigid. The handling of everything with forceps is a little awkward at first but dexterity is soon acquired. Good team work, with a thoroughly trained, conscientious surgical nursing sister and two intelligent orderlies, combined with rigid "joint" asepsis, has given us surprising results.

AMONG the rectors of the Italian universities nominated for the academic year, 1917-18, are two representatives of medicine. These are Dr. Roberto Binaghi, professor of clinical surgery in the University of Cagliari, and Dr. Pio Colombini, professor of dermato-syphilology in the University of Modena.

THE TREATMENT OF WOUNDS BY FLAVINE.

BY

E. M. PILCHER, F.R.C.S., D.S.O., COLONEL A.M.S.

AND

A. J. HULL, F.R.C.S., LIEUT.-COLONEL R.A.M.C.

We have seen lately in the *Lancet* and *BRITISH MEDICAL JOURNAL* two articles impugning the value of flavine and its congeners as antiseptics; and as we have used it largely in military practice and are confirmed in our good opinion of it as time passes, we think it would be something of the nature of an act of ingratitude if we allowed an excellent wound dressing to fall into discredit for want of support from its friends.

The first of the articles referred to takes flavine from the laboratory point of view and criticizes the technique by which its efficacy as against bacteria *in vitro* was established. With these points we may leave Dr. Browning and his collaborators to deal. But the second article, which appeared in the *BRITISH MEDICAL JOURNAL* of December 29th, 1917, and which takes us to the bedside of some fifty selected cases, we feel more competent to criticize. Its lucid exposition and fair and candid treatment of the observed facts make it easy to do so.

Two main theses are proposed in this article. First, a comparison is made between flavine and Carrel-Dakin treatment, in which the former, though not inferior at all points, is yet made, on the criteria chosen, to take a second place; and secondly, by histological examination flavine is shown to delay the process of repair, to allow organisms to remain on the wound surface, and to prevent epithelial ingrowth.

Now we hold that a comparison of any method with that of Messrs. Carrel and Dakin is not quite fair until the following facts are remembered: When these workers first showed that infected wounds could be cleansed by continuous washing with hypochlorite solution, they also pointed out the great difficulties of the method, the meticulous care required in the preparation of the reagent, in the protection of the surrounding skin, in the surgical ritual of the dressing, and so on. More than this, they were the first to set the ideal of ultimate wound suture, for we are sure no English surgeon had ever thought it possible before. Both these points—the difficulty of technique and the high ideal of repair—are characteristic of the Carrel-Dakin method, and explain why, though it is one of the most brilliantly successful ways of treating infected wounds in war, it is also one of the most difficult to carry out to full success. It is only in certain hands that it is really successful, and when it fails it fails badly.

One of us, who has opportunities of constantly visiting ten large hospitals, is prepared to affirm that not 10 per cent. of the surgeons whose work he sees have the requisite time in periods of stress, even though they possess the requisite patience of technique, to achieve anything like, for example, the success of the series of fifty cases quoted in this article. In making the comparison between the two series, the authors have heavily weighted the scales against the Carrel-Dakin method. This series is made up of "much more seriously wounded men," including cases considered too severe for experimental treatment with flavine, and the wounds submitted to the flavine treatment had previously for the most part been treated by the Carrel-Dakin method, and yet nearly double the percentage of suture cases is shown, the number of cases evacuated healed is two and a half times as many, and so on. This is plainly a series which has been in the hands of a master.

But to any observer who has opportunities of seeing the Carrel-Dakin method as performed by many hands, the above results seem a triumph of method indeed, but above all a triumph of individual technique. Results which we assert can only be obtained by an expert with much time and comparatively few cases are contrasted with a method which, to take a phrase from mechanics, is practically fool proof, for we suppose that, allowing adequate previous surgical treatment, any dresser can fill a wound cavity with gauze dipped in 1 in 1,000 solution of flavine.

We can only say that in the many hundreds of cases (rather more than 5,000 at present) so treated in the hospitals under the command of one of us, we have found

that for ease of preparation and application, rapidity when dealing with large numbers of cases, complete absence of surgical fidget, early cleaning of the wounds, and abatement of constitutional reaction to absorption, flavine (and its congener brilliant green) is an admirable application under all circumstances, but especially where surgeons are few, time is short, and wounds are many. But, even when contrasted with the Carrel-Dakin series, the series of fifty flavine cases does not come badly out of the test. We note that temperature falls early; that more than one-third reach the difficult suture ideal; and that, though there is delay in the process of healing, there is some diminution in the local and general reaction to infection.

We remember, of course, that the flavine series was in the same capable surgical hands as the other series, though this consideration must be discounted by the greater ease of application of flavine dressings. To sum up our criticism: we hold that, putting aside any question of the permanence and effectiveness of the antiseptic solution used in the Carrel-Dakin treatment (though this has been called in question), the method itself is not of universal application, entirely on account of its inherent difficulties of technique. If this is allowed, any simpler method which can be effectively used by less skilled workers, and which approaches in efficiency, as judged by the suture standard, the Carrel-Dakin method, is worthy in spite of minor drawbacks, of an extended trial in the army. We claim to have already passed through such a trial, and have made up our minds on the point. It only remains to add that in the 5,000 or more wounds under our observation no skin irritation has been observed, and we suggest that it is possible that the irritation observed in the cases quoted was due to the previous treatment by the hypochlorite method.

Coming next to the histological part of the article quoted, the appearances observed in the excellently reproduced series of sections given is conclusive evidence of a certain amount of surface destruction in wounds treated by flavine. This is clinically apparent in a few cases only in our experience. In these cases a fibrinous pellicle forms in the wound, and we have always been used to attribute this appearance to the use of too strong solution. There are no doubt individual idiosyncrasies with this as with any other application. Flavine, unlike other antiseptics, is not reduced in power by contact with serum, and therefore the evaporation of fluid may result in a concentrated mass action upon the tissues. We have found that the pellicle in question is readily removed by the application of saline solution. The lethal concentration of flavine against cocci in the presence of serum being 1 in 200,000 (Browning), we find the addition of hypertonic saline solution a valuable adjunct to the action of the antiseptic by producing free exudation; but allowing the fact of a microscopical layer of surface destruction, is it not a fact that all antiseptics are to some extent escharotic and produce in certain concentrations similar appearances? What we wish to know is—what is the exact clinical value of these observations? We are told that healing is delayed, that epithelial ingrowth is prevented, that organisms linger in the wound, and we find it extremely difficult to make these deductions from histological appearances square with our clinical experiences in thousands of cases. We are told gravely that "the employment of flavine and other dyes, as if they supplied royal roads to success, must be regarded as retrograde steps," and we go round our wards and find patients with normal temperatures, with no signs of constitutional reaction, with healthy granulating wounds, over which epithelium is growing naturally, and we wonder why the experience of the authors of this article was so different in fifty cases from our own in as many hundreds.

DR. LUIGI LUCIANI, the distinguished professor of physiology in the University of Rome, lately retired under the rule as to limit of age. He was born at Ascoli-Piceno in 1842. He was professor of pathology at Parma, and of physiology at Siena and at Florence before his call to Rome in 1894. His treatise on physiology has been translated into several languages. A review of the last volume of the English translation was published on January 5th. He is a Senator of the Kingdom of Italy, and as a Member of the Superior Council of Public Instruction he has done much during the past forty years for the improvement of medical education in his native country.

WOUND FLORA IN RELATION TO SECONDARY SUTURE.

BY

CAPTAIN A. R. MUNROE, M.D. MCGILL, C.A.M.C.,
SURGEON TO NO. — CANADIAN GENERAL HOSPITAL;CAPTAIN A. G. FLEMING, AND CAPTAIN R. M. JAMES,
M.B., D.P.H. TOR., C.A.M.C., M.B. TOR., C.A.M.C.,
PATHOLOGISTS TO NO. — CANADIAN GENERAL HOSPITAL.

I.

THE sterilization of septic wounds followed by secondary suture or closure, having for its objects the shortening of the patient's stay in hospital and the lessening of impairment of function, is the ambition of most army hospitals to-day.

Many brilliant successes have been recorded by those following the various methods in vogue. Several, on account of a few failures, have become sceptical about the results claimed by others, and have drifted back to pre-war methods.

An analysis of failures often teaches us much. The flora of all septic wounds consists of a conglomerate variety of bacteria—staphylococcus, streptococcus, *pyocyaneus*, *welchii* group, and bacilli with end or central spores, etc. On analysing fifty cases of secondary closure it has been noted that in all failures the anaërobic culture showed we had previously had to deal with a very active infection, which digested the meat medium rapidly and gave off abundance of gas with rotten-egg odour. The cultures obtained showed in some cases infection by an active streptococcus, in others by a spore-forming bacillus. In both cases, even when the bacterial count was low, the wounds so infected broke down on secondary suture. On the other hand, where the cultures obtained showed an absence of these particular groups of bacteria, and the meat medium was unchanged, wounds were closed successfully, even when affording a comparatively high bacterial count (20 to 30 per microscopic field).

Sufficient data are not yet before us to state definitely that all infected wounds might be classified clinically according to the findings of the anaërobic culture, but we have gone far enough to be of opinion that where the anaërobic culture shows a virulent infection, and where the culture obtained shows spore-forming bacilli, it would be advisable not to attempt secondary suture until the wound is absolutely sterile.

II.

After making many bacterial counts as a routine procedure in wounds, especially those which were being treated by the Carrel-Dakin method, it appeared that although the factor of the bacterial count was not an absolute guide it was of very considerable help, and a fair indication as to the progress of the combat between the tissues and the infection. Nevertheless, it seemed that other factors came into play, and it occurred to us that possibly the most important of these was the particular bacteria present in a particular wound. Accordingly it was decided to make cultures from a series of wounds with a view to determining the total bacterial flora of each, both aerobic and anaërobic.

A swab is taken from the wound either the day following or, in cases where the wound is very dirty, within two or three days after the patient arrives in hospital from France. This is planted in nutrient bouillon and in the meat medium recommended by the Tetanus Committee for the growth of anaërobics.

It seems advisable either not to inactivate the meat medium after inoculation with a view to eliminating all but spore-forming organism, or, if this be done, to run two cultures, one of which has been inactivated and one not, as the action of the facultative anaërobics on the medium appears to afford a clue to the virulence of the infection.

The broth culture is examined at the end of twenty-four hours and the findings recorded. The anaërobic culture is examined daily as to the bacteria present, colour, gas formation, digestion and odour, and the findings recorded. These examinations are carried out until it is apparent that nothing more is to be gained. A culture which has at any time shown *B. welchii* or bacilli of the malignant

oedema group is usually carried on for two or three weeks unless the bacilli of the end-sporing group appear before this time.

In attempting to judge of the virulence of the streptococci attention has been paid to the effect on the meat medium, the length of the chains formed, and the extent to which the streptococcus dominates the culture. Certain forms of streptococci rapidly digest and darken meat, produce gas, and even a disagreeable odour. These are considered virulent. Others, although a good growth is obtained, leave the medium unchanged. These have been regarded as the less virulent. Along with streptococcus, the *B. welchii* is found almost constantly, and in doing bacterial counts this organism in many instances accounts for a large percentage of the bacteria counted, although it would not appear to be an important factor in the healing of the wound. Streptococcus is the most persistent of all organisms we have found.

The malignant oedema group of organisms has been active on the meat culture, rapidly digesting it, forming gas, darkening it to brownish-black or even black, and producing an extremely disagreeable odour like that of rotten eggs. These have been regarded as a dangerous infection, even in the presence of a low bacterial count. The fact that the bacillus of malignant oedema may, in a non-inactivated culture, occasionally be mistaken for one of the *B. welchii* group, does not seem to be of great practical importance, as the identity of the malignant oedema group is later shown by the formation of the typical spores and the effect on the medium. Further, there is undoubtedly such a relationship between the occurrence of the two groups that where *B. welchii* is found one would hesitate in saying the other group is absent.

End-sporing bacilli, oval and round, have been found in a small percentage of cases. Among these may be mentioned a stump which repeatedly broke down, and a replating of femur for malposition, which broke down although the original wound had been completely healed for a period of six months.

It is within the power of many if not most of the laboratories now attached to our general hospitals in England to make cultures from almost if not all wounds in the hospitals where a secondary suture is likely to be undertaken. It is in the cases which early show a low bacterial count that the kind of organism present is of prime importance. At the end of a week or ten days the culture will have shown whether or not there is an extensive or virulent infection present, which it is probably not going to be advisable to close in by secondary suture.

THE VALUE OF A MIXTURE OF CYLLIN,
IODOFORM, AND OLIVE OIL IN
INTRATHORACIC SEPSIS.

W. GORDON, M.D. CANTAB., F.R.C.P. LOND.,

AND

M. E. GATES, M.D., B.S. LOND.

MEDICAL OFFICERS, NO. 1 SECTION, EXETER WAR HOSPITALS.

A CASE of pulmonary gangrene, apparently cured by post-operative injection into the lung tissue of the following mixture, was published by one of us (W. G.) in 1912:¹

R. Iodoform	gr. v
Cyllin	℥ v
Ol. olivæ	3ss

We now desire to report two cases of intrathoracic sepsis in which the same mixture has proved of undoubted service.

CASE I.

Cpt. R. L. was admitted from overseas on September 14th, 1917; he had been seized with pains in the left side of the chest on July 25th, and on August 14th a fetid empyema had been opened and drained. On admission his temperature was 102° and the next day 103°. The discharge from the wound was copious and most horribly offensive. The wound was packed with gauze soaked in the above mixture. Chart 1 shows the result on the temperature. The offensiveness of the discharge ceased immediately; there was no bad smell next day or afterwards. The dressing with the mixture was continued until his

transfer to a convalescent home in excellent condition with his wound nearly healed. The drainage, however, having been

CHART 1.—Cpl. R. L. C = Cyllin, iodoform, and olive oil begun.

imperfect, on November 15th a larger piece of rib had to be removed, by Mr. Ellis Pearson, surgeon to the section, after which progress was uneventful.

CASE II.

Pte. W. W., admitted March 11th, 1917. Twelve years previously he had a left-sided empyema, which was drained. About a month before admission he had an attack of pleurisy in the left side, and the old wound reopened and discharged. On admission the temperature was irregular, and there was dullness at the left lung base, so on March 25th the wound was enlarged by Mr. Pearson, and better drainage established. On March 31st severe haemorrhage occurred from the wound and

CHART 2.—Pte. W. W. O = Operation. H = Severe haemorrhage. C = Cyllin, iodoform, and olive oil begun.

continued to a considerable extent. The temperature, which had fallen after the operation, rose again to 102° on April 2nd. As the condition was obviously one of intrathoracic sepsis, injection of the cyllin and iodoform mixture was begun and continued, with the result shown on Chart 2. The haemorrhage ceased, and there was no further rise of temperature until April 14th, when the patient had a slight rise of temperature accompanied by slight haemorrhage lasting about two days, after which recovery was uneventful. The patient is now very stout and well.

We have since seen a third case of intrathoracic sepsis following a gunshot wound, in which the use of this mixture has been of great value.

MUTTON BIRD OIL.

BY

LIEUT.-COLONEL J. S. PURDY, D.S.O., M.D., C.M.ABERD.

D.P.H.CAMB., F.R.S.E., A.A.M.C.

FELLOW ROY. SAN. INST., METROPOLITAN M.O.H., SYDNEY.

As cod-liver oil is difficult to obtain in sufficient quantities it may be of interest to know that the oil extracted from the sooty petrel is not only an excellent substitute, but, in the opinion of some, more effective in the treatment of bronchitic conditions and phthisis.

The sooty petrel, which is known in New Zealand and Australia as the mutton bird, spends nine months of the year in the Antarctic, and, consequently, must be so constituted as to stand extreme degrees of cold. The birds arrive in enormous numbers at their breeding places on Stewart Island, to the south of New Zealand, and on the islands in Bass Straits. The chief islands on which they breed are Chapple Island, Hummocky Island, Tin Kettle Island, and the other small islands near Flinders Island and Cape Barren Island. These birds arrive on the same day every year, and depart in flocks at the end of their period of migration.

The female lays only one egg, which is hatched by the parents sitting in turn. The young birds are fed by the parents with marine life collected from far at sea. When about six weeks old, the young, which are found in burrows similar to rabbit holes, are taken by the residents and half castes who visit these islands for the mutton bird season. The young bird is lined with fat, which is expressed as oil. The birds are then gutted, salted, and smoked, and used to be sold in Tasmania and New Zealand at a retail cost of 1½d. to 2d. each, and in Sydney at 6d. each. Recently a certain number have been tinned for export; some have reached the western front, and have been much appreciated as an article of diet.

In 1900, whilst in practice in The Hutt, New Zealand, I found at Porirua and Otaki, in the Maori Pahs, that natives suffering from consumption in some cases put on flesh during a tangi, which is something akin to an Irish wake. At these times the natives consumed large quantities of mutton birds.

At Tawa Flat, where some Norwegians had settled, I induced two of the settlers, who were suffering from phthisis and did not object to the fishy taste of the mutton bird, to eat one mutton bird a day, and found after some months that there was a considerable increase in weight. I published a paper in 1900 in the *Australasian Medical Gazette* advocating the feeding of cases of phthisis with mutton birds. In 1910, on going to Tasmania as chief health officer, I found on the west coast of Tasmania a chemist at Zeehan who was putting up an emulsion of mutton bird oil and almond oil, which had earned a considerable repute for the treatment of bronchitis and phthisis.

On visiting the islands in Bass Straits with the then Governor of Tasmania, Sir Harry Barron, Sir Elliott Lewis, the Premier, and other members of the Ministry and Government officials, I found that the mutton bird was one of the principal articles of diet among residents of the islands. Later, in 1913, I was marooned on these islands for six weeks, whilst investigating an epidemic of what I diagnosed as atypical measles simulating scarlet fever, but what Dr. Wetter of the Mawson Expedition diagnosed as atypical scarlet fever simulating measles; my chief article of diet, as of the others, was mutton birds, and I found a progressive increase in weight.

On behalf of the Tasmanian Government, the Commissioner of Police, Colonel J. E. C. Lord, D.S.O., made a special report on the mutton bird industry. As a result, I understand that improved conditions have been introduced into the islands and that these birds are sufficiently protected to prevent any serious diminution in their numbers.

The supply of oil from this source is considerable and would be a valuable addition to the medicinal oils at the present time.

Another point of interest about this industry is that, until a German agent intervened, the feathers, owing to their oily state, were found to be a nuisance, but previous to the war were actually exported to Germany, where they were treated and used in the making of cushions and pillows.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PERICARDIAL KNOCK.

A FEW days before the appearance of Colonel S. Maynard Smith's article in the *JOURNAL* of January 19th, p. 78, I was called to see a boy who had been accidentally shot in the head and left side of the chest when rabbiting.

About an hour before he died a loud cardiac "click" developed which was synchronous with the heart systole and could be heard distinctly six or eight feet away. It bore no relation to the respiratory movements, as the respiration was Cheyne-Stokes in character and the sound persisted during the period of apnoea. The simile of the click in the ear-piece of a telephone when the lever is

raised illustrates it very well. During the last fifteen minutes of life the heart became very feeble and irregular and the "click" disappeared. I was very interested to read Colonel Maynard Smith's explanation of the phenomenon, as I was quite unable to account for it. A *post-mortem* examination was not ordered by the coroner, so no further investigations could be made.

Ilminster.

W. P. HENLEY MUNDEN, M.D.Lond.

A SERIES OF CASES OF TYPHUS FEVER.

OSLER points out that a remarkable feature of typhus fever is that a few cases may occur in any locality; this has led some to believe that it can originate spontaneously. Recent experience of seven cases during a few weeks in a mining village, separate from any seaport town or contact with any military barracks, tends to corroborate this opinion, and also the view that the virus becomes reinforced as the epidemic increases, the prominent symptoms of typhus showing only in the later cases.

The first case in the series here reported was anomalous. The patient had all the symptoms of influenza, but by the fourth day a slight haemorrhagic rash had come out on the arms; the throat and mouth were very dry, the tongue baked, and later a fungus-like growth filled the roof of the mouth. Swallowing became impossible, and I suspected an acute suppurative condition of the oesophagus. The pulse at the wrist was imperceptible and vomiting very prominent. The second case showed early prostration, with high temperature, delirium, and cardiac failure by the fourth day, when there was a rash all over the body, but not typical. The third patient had all the above symptoms; the rash was more typical but was not present on the face. This patient developed bronchopneumonia. She lay on her back in muttering delirium with the typical flushed face of typhus.

The other cases became more typical; the rash came out first on the extensor surfaces of the arms and lumbar region of the back, and gradually covered all the body, the face and even the ears being well covered by the fourth day. The rash resembled rubella, but there was typical subcuticular mottling. The rash looked as though one were looking through a dim glass at it. Epistaxis was present in one case and retention of urine in another; the conjunctivae were injected in the last two cases. A specimen of blood from two of the patients was very dark and fluid; in fact, I had difficulty in stopping the oozing in one case. The blood gave a positive Widal reaction in three cases and a partial agglutination in two other cases.

The early dry and dirty tongue and throat, together with the early prostration and cardiac failure, made me suspect typhus fever even when the rash was not typical. The cases had no distinct odour. In all the onset was abrupt; constipation was present during the whole illness, which terminated in a crisis about the twelfth or fourteenth day. The patient who developed bronchopneumonia and typical flushed face died.

JOSEPH STARK, L.R.C.P., L.R.C.S.Edin.

Winchburgh, West Lothian.

PENETRATING GUNSHOT WOUND OF THE ABDOMEN IN CIVILIAN PRACTICE.

A PARTY of boy scouts were practising rifle shooting at a miniature range on November 18th, 1917. When E. M., aged 15, who was in charge of the party, was changing the targets at about 1 p.m., another scout fired and hit E. M. in the abdomen. He was admitted to the Reigate and Redhill Hospital at 2.45 p.m. His condition on admission was fair, though he was blanched and somewhat collapsed. The pulse was 130. There was a bullet wound $1\frac{1}{2}$ in. to the left of the upper border of the umbilicus.

He was immediately taken to the theatre and the abdomen opened. The peritoneum was found to be full of blood; two mesenteric vessels were seen to be bleeding, and there were two perforations of the small intestine. The mesenteric vessels were tied. The perforations, which were in the coil of intestine immediately above the coil in which the mesenteric vessels were divided, were side by side, $\frac{1}{4}$ in. from one another. This coil of intestine was plated to enclose both perforations with two layers of Lembert sutures. A small slit in the mesocolon was stitched up. The bullet was not seen. A big tube was

put into the pelvis, the original wound excised, and the abdomen stitched up. Some subcutaneous transfusion was required during the operation. With the exception of paralytic diarrhoea lasting for three days there were no complications, and the case has now been discharged as cured.

I am greatly indebted to Mr. Pegg and Dr. Crichton (late R.A.M.C.) for their kind assistance, and to Dr. Chave, who subsequently localized the bullet by *x* rays, lying against the body of the left ilium.

Reigate.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

GENERAL MILITARY HOSPITAL, EDMONTON.

A CASE OF INTESTINAL OBSTRUCTION DUE TO BURIED SWABS.

(By D. M. HUGHES, M.B.Lond., F.R.C.S.Eng., Major R.A.M.C., Officer-in-Charge, Surgical Division.)

PRIVATE M., aged 21, was admitted to hospital with the following notes on his field card: "Wounded November 14th, 1917, right side of back. Laparotomy November 15th, foreign body extracted from the liver to the right of the gall bladder, having passed through the upper pole of right kidney. No intestinal injury found." On admission to Edmonton, on November 30th, the patient was quite convalescent, and taking ordinary diet.

On December 15th he was seen by me on account of vomiting and pain which had come on suddenly the previous night. The abdomen was flaccid except in the middle portion of the abdominal scar—a very long and beautifully healed incision extending nearly from the ensiform to the pubes. Behind the umbilicus, however, there was a rigid area too tender to permit of deep palpation. Elsewhere free manipulation was possible, and nothing abnormal found. The vomit was faeculent, and the pain spasmodic, rising to a climax and suddenly ceasing, though the intervals between the spasms were clearly becoming shorter. Temperature 97° F., pulse 112. The symptoms were so unequivocally those of intestinal obstruction that immediate operation was decided upon.

Ether was administered by Lieutenant Simon, and with the assistance of Dr. F. W. Carter an incision six inches long was made through the old scar; the intestine and omentum, the latter especially, were found adherent to the abdominal wall in the line of the incision; they were readily separable. A collapsed coil of intestine rapidly passed through the fingers ended in a globular mass of agglutinated intestine and mesentery the size of a large orange. Coils of dilated and injected intestine obscured the mass, but the dilated bowel was easily traced into it. The unravelling of the mass was difficult, as it had to be done in the depths of the abdomen among dilated coils. Moreover, the adhesions between the coils were completely organized, had to be separated with the knife, and hence bled freely. Two perforations were thus encountered (probably caused) and were treated with purse-string sutures, slight faecal soiling inevitably occurring. As the mass was unravelled the core was seen to be formed by two grey-green swabs smelling strongly of faecal matter. The intestine set free from its adhesions measured about 12 in. in length, and was brought out of the abdomen and examined, bare areas being covered by cross stitching. A stab wound in the middle line above the pubes liberated a quantity of blood-stained fluid, and a large cigarette drain was passed into the pelvis; the patient was immediately placed in the Fowler position; he left the operating table with a pulse of 144, but rapidly improved, and his further recovery was uneventful.

The case is of interest from the effort made by nature to encapsule the swabs. Usually this devolves upon the omentum, but presumably the omentum being small and denied access to the offending swabs by reason of adhesions to the line of the previous abdominal incision, the encapsulation of the foreign body was carried out by the coiling of the intestine about it.

Reports of Societies.

THE MENTAL FACTOR IN SPA TREATMENT.

To a meeting of the Section of Balneology and Climatology of the Royal Society of Medicine on January 31st, when Dr. PRESTON KING, the President, was in the chair, Dr. PERCY LEWIS, of Folkestone, contributed a paper on this subject, in the course of which he pointed out that in all chronic illness increased attention was consciously or unconsciously given to the diseased part, and must be again diverted into normal channels. Thus was explained the better results from foreign than from British spas, owing to the increased interest in novel surroundings. British health resorts were urged to copy in this respect. It was only by diverting attention from inside (introspection) to outside that the mental abnormality could be cured. The personality of the spa physician as a most important element in the cure was considered, and it was maintained that the success of a physician showed that he understood how to deal with the mental factor. The effect of religion as a means of cure was held to depend on its power of exciting the necessary great expectation of cure, aided by the element of mystery. Finally a plea was made for the claims of all forms of suggestion, hypnotic, hypnoidal, or waking persuasion, and for a systematic study of the cures which have taken place by most diverse means through all ages, thus fixed principles might be elucidated allowing of scientific application. The PRESIDENT was glad to hear the introspective habit discouraged; it could be avoided by occupation, and on this account he disapproved of the typical rest cure. Dr. CAMPBELL McCURE said that the music and theatres, even at our largest spas, compared very unfavourably with similar entertainments at Continental spas. At our English resorts there was little to take a patient's mind off himself and his ailments, whereas the mental factor was well catered for on the Continent. Dr. F. HERNIMAN-JOHNSON expressed strong disapproval of the use of electrical treatment for its mental effect.

THE VAGINAL DOUCHE.

At the annual meeting of the North of England Obstetrical and Gynaecological Society, held in Manchester on January 18th, Dr. FLETCHER SHAW (Manchester) described three cases: (1) *B. coli* cystitis producing intestino-vesical fistula; (2) a case of thrombosis of the mesenteric veins with symptoms simulating a twisted ovarian cyst; and (3) a case of strangulated intestine with symptoms simulating an ovarian cyst with twisted pedicle in a patient aged 42. Dr. W. E. FOTHERGILL (Manchester) introduced a discussion on the use and abuse of the vaginal douche. He took up the position that it was a curse rather than a blessing. The antiseptic douche was inferior to the methods of dry cleaning now in use when the object was to destroy pathogenic organisms; and when used without discrimination it was pernicious in several ways. The so-called hot douche, intended to reduce pelvic hyperaemia, was not used, in practice, hot enough to cause the desired effect. As used it was really a warm douche, and increased pelvic hyperaemia. This was useful under certain circumstances—namely, when the absorption of inflammatory exudates had to be aided. This indeed was the only useful purpose for which, in his opinion, the douche could be used. Drs. DONALD, GEMMELL, WILLET, and others took part in the discussion, and the opinion generally expressed was that the habit of indiscriminate douching by women is bad, that the antiseptic douche is of questionable value, and that the warm douche, used with the same objects as a poultice or hot fomentation in inflammatory conditions, is useful.

THE address on nursing ethics, first published by Dr. Kirkpatrick, Registrar of the Royal College of Physicians of Ireland in 1915, has been reprinted. Copies can be obtained on application to him at 6, Kildare Street, Dublin, price 1s. net. The lecture, of which we gave some account in the JOURNAL of February 13th, 1915, p. 302, is dedicated to the nurses of Dr. Steevens's Hospital, past and present. It contains much advice which will be valuable to all nurses.

Reviews.

LEISHMANIOSES.

A NEW work on leishmanioses,¹ by Professor LAVERAN, resembles in style and appearance his well-known book on malaria, and as he has already dealt with trypanosomiasis in conjunction with Professor Mesnil he has now provided treatises on three of the main tropical diseases. The new work contains 521 pages and is illustrated by a few coloured plates and by photographs and diagrams. Since 1903, when the specific parasite of kala-azar was first discovered, enormous strides have been made in the elucidation of some of the problems raised by this class of diseases, and at the same time an extensive literature has come into existence. Professor Laveran therefore has rendered a great service in making all these details available in an easily accessible form. The book is written in his usual lucid style; it is accurate and contains everything that is required to be known about the subject to-day. It contains five main sections: (1) Leishmania and leishmanioses in general. (2) Human visceral leishmaniosis or kala-azar, of which the agent is the Leishman-Donovan body. Infantile kala-azar, which was at one time considered a separate disease, is now included under this heading, as the author considers it to be identical with the adult form. (3) Natural visceral leishmaniosis of the dog, probably of the same nature as kala-azar. (4) Cutaneous leishmaniosis or *bouton d'Orient* (oriental sore), due to the *Leishmania tropica*; and (5) American leishmaniosis of the skin and mucous membranes, which is described as a variety of the common variety of cutaneous leishmaniosis (oriental sore). These divisions are then described in detail, references to the literature mentioned being placed at the foot of each page. These references are very full and seem as far as we can judge to be complete. The use of the termination -osis is open to the objection that -asis is used for other diseases of tropical origin (ankylostomiasis, bilharziasis, distomiasis, trichocephalasis). A rather serious defect, common in French works, is the absence of an index. In a book such as this, which the practitioner and laboratory worker in the tropics will wish to use as a work of reference, this is most inconvenient and considerably militates against its use for this purpose. It is difficult enough to find the main headings, but the search for smaller details calls for the expenditure of so much time that few will have the patience to make habitual use of the book. As the text is so valuable it would repay translation into English and if a table of contents (also missing in the French text) were added, as well as a good index, the value of the volume would be greatly enhanced. The parts of the book dealing with treatment are most interesting, for here great progress has been made. Machado and Vianna in South America first tried intravenous injections of antimony in cutaneous cases of leishmaniosis, and the success obtained was so great that the method has been applied by many workers in different parts of the world, both in the cutaneous forms of the disease in Asia, and in the form known as kala-azar. Results, better than by any other method of treatment, have been obtained, and thus the disease has been robbed of many of its terrors. There are still, however, many points requiring elucidation; there is, for example, scope for much original investigation into the way in which the disease is spread from person to person. To any one wishing to tackle these problems, Professor Laveran's book will prove invaluable.

The volume by Dr. BRAHMACHARI of Calcutta, entitled *Kala-azar and its Treatment*,² gives a full account of his clinical experience in the use of various antimonial preparations in the treatment of this disorder, which is a chronic infectious form of leishmaniosis occurring in India. Before doing so he passes in review the various methods of treatment which have not proved satisfactory in the past, including French and Italian attempts to produce a

¹ *Leishmanioses: Kala-azar, Bouton d'Orient, Leishmaniose Américaine*. By A. Laveran, Professeur à l'Institut Pasteur. Paris: Masson et Cie. 1917. (Roy. 8vo, pp. 521; 40 figures, 6 plates. Fr. 15.)

² *Kala-azar: Its Treatment*. By U. Brahmachari, M.A., M.D., Ph.D., Rai Bahadur. Calcutta and London: Butterworth and Co. 1917. (Demy 8vo, pp. v + 121; 6 plates, 17 charts. 8s. 6d. net.)

vaccine. He describes promising results from the use of organic arsenic preparations and from intravenous injections of antiseptics, such as iodine, quinosol, formaldehyde, and ammonia picrate, but he had his most striking successes in the treatment of Indian kala-azar with antimonial preparations. These preparations, of which a considerable number is enumerated, have been variously administered by the mouth or rectum, by intravenous or intramuscular injection, and by innunction. Each method has its advantages and disadvantages. Speaking generally the intravenous method is best, but Dr. Brahmachari hopes that before long some mode of injecting antimonial salts into the muscles without causing pain may be discovered. After an extended trial of these various methods and preparations he comes to the definite conclusion that "antimony is specific for kala-azar, and of all its known preparations metallic antimony is the best," here including both colloidal and very finely divided antimony. The number of injections of metallic antimony required he finds to be much smaller than that of the various soluble antimonial salts he has tried. His latest observations go to show that alternating injections of antimony and one of the antimony salts (sodium or potassium emetic, for example) give excellent results. Among the troublesome symptoms that may follow intravenous injections of tartar emetic (up to perhaps 10 c.c. of a 2 per cent. solution?) he mentions pyrexia, rigors, intense headache, pain in the gums, cough, vomiting, and diarrhoea, pain in the abdomen and loins, oedema of the extremities, cardiac depression, and transient jaundice. But it must be remembered that this alarming list refers to the exceptions. His book contains records of a large number of cases treated with antimony and other drugs, and gives evidence of a very wide experience in the treatment of kala-azar.

THE CONTINUITY OF SOCIAL LIFE.

THE title of Mr. COULTON's volume, *Social Life in Britain from the Conquest to the Reformation*,³ is rather deceptive. It might suggest a historical essay which would be rather dry reading, but his compilation is as diverting as it is informing. It may perhaps best be described as a commonplace book of extracts from contemporary writers, chosen and classified with a well defined object—that of supplying the "background of social history which is necessary to a sympathetic comprehension of our own literature in the Middle Ages"; but he has done more than this, whether he set out to do so or not, for he is able to claim with truth that in his extracts our forefathers are found speaking for themselves on the main questions which interest people to-day. It is a fascinating book; not one to read through, but to take up at odd times, so that gradually the point of view of the English in the thirteenth and fourteenth centuries, the period for which it is richest, is borne in upon the mind. There is, for instance, the Act of 1388 for "the punishment of them which cause corruption near a city or great town to corrupt the air." There had been local ordinances of different boroughs earlier, but this is believed to be the first urban sanitary Act for the whole of England. It was a short Act, as easy to be understood as it was probably difficult to enforce. Those who did not obey it were liable to the smart fine of £20, equivalent to, perhaps, £300 or £400 in modern currency, and this liability applied not only to the actual defaulter, but also to the mayor and bailiffs who failed to put the law in force. It also empowered any person aggrieved, whether a citizen or merely a person who frequented the town, or any traveller, to set the law in motion. In the local ordinances which preceded the general law we have an early illustration of the fact, evident to-day, that advances always come from the local authorities. The London ordinance was made in 1281, over a century before the Act was passed. With the more rapid progress of modern thought the interval has been reduced to half a century, or even less.

Coming to the early fifteenth century (1410) we find the record of how the wife of Hiky, the poulterer, who charged 20 pence for four woodcock, and the wife of John Mede who refused 12 pence for two partridges, contrary to the food tariff, were committed to prison. Four years ago the

incident would have seemed wholly mediaeval; but like causes continue to produce like effects.

As to the sixteenth century, is there not something very modern about the following passage from a memorandum (1530) on the management of his school made by the master of Eton for the information of the master of Saffron Walden Grammar School: "When any dothe come newe, the master doth inquire fro whens he cometh, what frendys he hath, whether there be any plague." By the last word is probably to be understood any epidemic disorder.

Perhaps the most lasting impression left by an hour or two with the book is of the similarity and continuity of the life of Britain to-day and in the thirteenth and fourteenth centuries. At first the changes may strike the reader most, but as he reads on, foregoes laughing at the spelling, and grows into the spirit of the age, he sees that the essential fundamental qualities of the race, its habits and methods, have not changed.

NOTES ON BOOKS.

CAPTAINS C. G. MOOR and E. A. COOPER, R.A.M.C.(T.), in collaboration with officers and men of the 1st London Sanitary Company, have compiled an excellent little handbook on *Field Sanitation*,⁴ written in a practical spirit, and covering the ground very thoroughly. We cordially endorse the hope expressed in the author's introduction "that combatant officers will use this book, which is written quite as much for them as for those whose whole time is occupied in sanitary work." Major H. S. Fremlin, the commanding officer of the unit, points out, in a short preface, that the instructions contained in this volume are the outcome of many changes in sanitary work and appliances that have developed during the war, and that for this reason it should be considered in the light of an appendix to existing works. He draws particular attention to the chapters on baths and laundries in the field, on the disposal of excreta and refuse, and on the methods for economizing public money. Throughout the book directions are given for improvising sanitary appliances out of simple and handy materials, and working sketches show clearly how the apparatus described may be constructed. The authors are to be congratulated on producing a lucid, well arranged, and interesting guide to the means for keeping men healthy and comfortable on active service.

Captain W. H. BROAD, M.D., R.A.M.C., medical officer in charge of the Massage and Gymnastic Departments and Curative Workshops, Alder Hey Military Orthopaedic Hospital, Liverpool, has issued, with the approval of Colonel Sir Robert Jones, Inspector of Military Orthopaedics, a leaflet, entitled *Rules for Massage*. In the rules for muscle cases Captain Broad points out that it is essential that a paralysed limb should not be allowed to lie in a position in which the affected muscles are stretched, so as to permit the undisputed antagonism and possible contraction of the opposing healthy muscles. The condition of slight contraction, constant in a normal muscle in order that it may respond instantly to an impulse, commonly spoken of as "tone," is absent in a paralysed muscle; it must therefore be kept from being stretched and elongated by the use of a suitable support. The necessary massage can, he says, often be done in these cases without removing the supporting splint, but, when its removal is essential, the limb must instantly be passively supported by a pillow or sandbag as the splint is withdrawn, to prevent any stretching of the affected muscles. The leaflet has a separate paragraph on joint, bone cases, and tendon transplantation. Instructions are given on note-making. Altogether the leaflet will be found a most valuable guide by the conscientious worker.

The scope of the book *Fifty Thousand Miles on a Hospital Ship*,⁵ by "The Padre," is well expressed in its title. It consists of budgets of letters, arranged in diary form, which the author, a chaplain on a hospital ship, sent home. Most of his service was spent in the Mediterranean in connexion with the Dardanelles expedition. The volume is well illustrated by reproductions of photographs, and gives a good picture of life on a hospital ship, often under trying circumstances.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the General Committee of the Belgian Doctors' and Pharmacists' Relief Fund was held at the house of the Royal Society of Medicine on January 31st. Sir RICKMAN GODLEE, who presided, gave an outline of the history of the Fund, and stated the procedure governing the dispatch of money and also, in the early days, of drugs and appliances to doctors and pharmacists in Belgium, and the granting of material or monetary relief to refugees in the United Kingdom. The funds available were now almost exhausted, but the executive felt that it was hardly possible to retire from the work at this stage, and it was for that meeting to consider what further appeal should be made.

Dr. H. A. DES VŒUX, the honorary treasurer, stated that since the opening of the Fund in November, 1914, the sum of close upon £20,000 had been received. Of this amount, £2,248 had come from Canada, £2,423 from Australia, and £1,638 from New Zealand, as well as smaller sums from South Africa and India, and from Denmark and Italy. The administrative expenses had amounted to £90 only, thanks chiefly to the ungrudging labour of his own secretary and to the help which had been given in the offices of the *Lancet*. With interest, nearly £21,000 had been available for distribution. The amount spent on the refugees in the United Kingdom was £611; part of this amount had been applied to paying the registration fees of Belgian doctors who wished to practise in this country. In March, 1915, £800 was sent to the Belgian committee—Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés—and similar amounts in June and July of that year; from April, 1916, the sum of £800 had been sent each month until December, 1917, when only £700 was sent; and January, 1918, when the donation was reduced to £400; only £400 was now left of the original fund. Dr. Des Vœux reminded the meeting in moving terms of what Britain owed to Belgium. Had it not been for Belgium's rejection of the biggest bribe in history and her heroic resistance to the invader, the Germans would have occupied the Channel ports, with disastrous consequences for the British empire. For his own part he felt it was their bounden duty to go on with such a fund as this.

Dr. S. SQUIRE SPRIGGE, one of the honorary secretaries, said that it was the unanimous feeling of the executive that a fund which had done so much for the credit of the profession should be continued. The minimum to be aimed at was £10,000. It was a question whether an appeal should be made to the general public, or first a more systematic appeal to the medical and pharmaceutical professions. He acknowledged the help of the British Medical Association in placing its machinery at the disposal of the Committee; this alone had made it possible to reach the more distant parts of the country and empire. But he felt that it might be advantageous to have a number of local secretaries who would distribute appeals and collect subscriptions in their own districts. It might also be possible to appeal to public bodies other than the medical and pharmaceutical corporations, which had already been addressed. There need be no misgiving as to whether the money sent to Belgium reached its objective; receipts were regularly received from the Belgian Committee sitting in Brussels, though since the rupture between America and Germany and the closing of the American channel of communication the analysed *comptes rendus* showing how the money had been applied were no longer available.

Sir A. PEARCE GOULD supported the appeal for the continuance of the fund, and suggested a system of monthly subscriptions.

Dr. DES VŒUX said that personally he was rather against an indiscriminate public appeal, for he would like, if it were possible, that this work should remain to the end within the two professions. It would be an additional honour if they could carry it through themselves as an act of sympathy with their Belgian colleagues.

Dr. ALFRED COX, Medical Secretary of the British Medical Association, proposed that a postal appeal should be issued to every member of the two professions; this was seconded by Mr. THOMAS MABEN, F.C.S., for the pharmacists, and was agreed to.

A vote of thanks was accorded to the ladies who had superintended the clothes bureau, which work was now merged into that of the War Refugees Committee; and an interim vote of thanks to the officers of the Fund and their clerical assistants.

SUBSCRIPTIONS.

Subscriptions received in response to the second appeal for the Fund up to January 30th:

THE MILITARY MEDICAL SERVICES IN 1917.

IN THE BRITISH MEDICAL JOURNAL of January 2nd, 1915, of January 15th, 1916, and of January 27th, 1917 (p. 124), were published articles on the military medical services in 1914, 1915, and 1916 respectively, dealing with their strength and their losses during these years. The present article continues the series for the year 1917.

The first two articles began with notes on the strength of these services, and their expansion to meet the demands of war. As no new *Army List* has been available to the public for the past two years and a half, the last issued for general use having been that of June, 1915, any consideration of strength must now be chiefly guesswork. A certain amount of information, however, has been given in two speeches by the Leader of the House of Lords and by the Viceroy of India, which are noted below in their place.

The mortality in the medical services during nearly three and a half years of war is briefly shown in Table I below. Medical officers of all services, and also medical

men serving as combatants, are included in this table. In both this and the following table officers who died of wounds or who were lost at sea by enemy action are included among the killed.

TABLE I.

	Killed.	Died.	Total.
1914 (five months)	46	?	46
1915	97	45	142
1916	162	98	260
1917	200	93	293
Total	505	236	741

In Table II are shown the numbers killed (including died of wounds and lost at sea), died while serving, wounded, missing, and prisoners in each of the medical services during the year 1917. The numbers shown as killed are believed to be correct, except that they comprise a few killed in 1916, and not included in the table for that year, and probably omit a few, not yet reported, who lost their lives towards the end of 1917. They are at least very near the truth. The numbers shown as wounded have been compiled from the daily casualty lists, as summarized weekly in the *BRITISH MEDICAL JOURNAL*. The figures are doubtless not quite exact, but they are approximately correct. Most of those reported as having died of wounds had been previously reported as wounded, and most of those shown as missing have been subsequently accounted for, either as killed or as prisoners, so that a certain number, small compared to the total, have been shown twice over.

In the absence of exact information as to the total numbers in each of the medical services, the proportion of killed and wounded in each can only be guessed at. In actual numbers the temporary officers of the R.A.M.C. are an easy first. But the total number of these officers is far greater than that of any other class. The proportion of killed to the total number of officers is probably higher in the Australian Army Medical Corps than in any of the others.

Throughout the year the seat of war in which casualties have occurred has not been officially stated, except in a few cases from Africa. The greatest number by far must undoubtedly have happened in France, though the Balkans, Mesopotamia, Palestine, and East Africa have all contributed a share.

TABLE II.—Casualties and Honours, 1917.

	Killed.	Died.	Wounded.	Missing.	Prisoners.	Honours.

I.M.S.	3	9	6	2	2	74
I.S.M.D.	—	7	—	—	—	18
Combatants	12	2	—	—	—	—
Miscellaneous	7	—	—	—	—	—
Total	200	93	626†	19	12	1231

* Including 3 lost at sea.

† In 1915 the number of medical officers returned as wounded was 224, in 1916 it had risen to 395, while in 1917 this figure was again greatly exceeded, with a total of 626. These figures are doubtless not exactly correct, but they are approximately so. Several officers first returned as wounded subsequently died of their wounds, and in a few cases the same officer has been wounded more than once during the year.

ROYAL NAVY MEDICAL SERVICE.

The number of medical officers on the active list of the Royal Navy is probably much the same as it was a year ago. The casualties and the number of new appointments have both been few. The number of temporary surgeons has probably slightly increased.

The number of naval medical officers killed has been fifteen, and of these eight, or ever one-half, have been surgeon probationers of the R.N.V.R. Three medical officers were killed when H.M.S. *Vanguard* blew up on July 9th.

ROYAL ARMY MEDICAL CORPS.

When proposing the vote of thanks to the Navy, the Army, the Colonial Troops, and the Mercantile Marine, in the House of Lords on October 29th, Lord Curzon, the Leader of the House, stated that, at the beginning of the war, the strength of the R.A.M.C. was 3,168 officers and 16,330 of other ranks; while, by the date of his speech, it had expanded to nearly 14,000 officers and 125,000 of other ranks. These figures give some clue to the present strength of the service. The figure of 3,168 in 1914 evidently includes Territorial officers, for the strength of the regular R.A.M.C. has never been much over a thousand. In the present total of nearly fourteen thousand the medical officers of the Royal Navy are evidently not included, and it is probable that the I.M.S. and the medical corps of the Dominion troops are also not counted.

The strength of the regular R.A.M.C. has somewhat increased during the year. In the *London Gazette* of January 10th, 1917, was notified the appointment of 104 Special Reserve, Territorial, and temporary medical officers to permanent commissions in the army. On the other hand, in the *Gazette* of December 25th, forty-eight senior officers were placed on retired pay on attaining the age limit. Adding thirteen killed, eight died, and five or six retirements on account of ill health, leaves a net increase of about thirty. The numbers of the Special Reserve, Territorial, and temporary officers have probably also somewhat increased, but this is mere guesswork. As regards the numbers of the Dominion medical corps no information is available.

Not knowing the total number, little can be said as regards the proportion of fatal casualties among the different medical corps. It appears, however, that the proportion of medical officers killed has been highest in the Australian forces. Still more remarkable is the number of Australian medical officers of the higher ranks killed. The number of medical officers of field rank killed during the year appears to have been eighteen, namely, regular R.A.M.C., four (of whom two were lost at sea); R.A.M.C. (T.F.), four; Australians, eight; Canadians and South Africans, one each; R.A.M.C. Special Reserve and temporary officers, I.M.S., and New Zealanders, none.

Of the medical men killed serving as combatants, two were lieutenant-colonels, and two were majors. One lieutenant-colonel was an Australian, the other three were in the Royal Artillery.

It was, of course, only to be expected that the casualties should fall chiefly on the junior ranks. Their numbers are immensely greater than those of the seniors. Also the medical officers most exposed to danger, serving with regiments and in the advanced dressing stations, are mostly officers of the rank of captain and lieutenant.

Sons of Medical Men.—The number of sons of medical men reported in the *BRITISH MEDICAL JOURNAL* as killed, while serving as combatants, in 1916 was 385. In 1917 the number reported was somewhat less, 338. In each case a few are included who were not killed, but died. The figures are doubtless very imperfect, especially as regards men serving in the ranks and in the Dominion troops.

Medical Students.—The number of medical students reported as killed in 1916 was 57, and in 1917 somewhat less, 35. Those who were sons of medical men are not included, having been shown under that head. Here also the figures are very imperfect.

Combatants.—At least six medical men and six dental surgeons were killed serving as combatant officers. One or two of these lost their lives in 1916, but were not reported in the *BRITISH MEDICAL JOURNAL* till 1917.

THE INDIAN MEDICAL SERVICE.

This service has been maintained at about its normal strength of rather under 800, the number of appointments

by nomination having just about balanced the wastage by death and by retirements for ill health.

The number of temporary officers at the beginning of 1916 was about 130, and by the end of that year had probably been doubled. In a speech delivered at Simla on September 5th Lord Chelmsford, the Viceroy, stated that the number of temporary appointments made had reached a total of nearly 500. This is nearly two-thirds of the strength of the permanent service. Probably, however, the figure of 500 includes all appointments made up to date. The wastage among temporary officers caused by resignations, by deaths, and by a few nominations to permanent commissions has probably by this time, after three and a half years of war, reached nearly a hundred.

One officer of the permanent service has been killed in action during 1917, and two temporary lieutenants were killed in Mesopotamia early in the year. Two other officers, Captains Arthur and Mukerji, who were among the prisoners taken at Kut, died in captivity during the year. No retired officer died while actually serving during 1917.

The service suffered a great loss during 1917 by the death, on October 21st, of its Director-General, Sir Charles Pardey Lukis. Originally appointed for five years on January 1st, 1910, he had received repeated extensions of service during the war; the last intended to run till the end of 1918.

The Indian Subordinate Medical Department.

In this service the names of commissioned officers only have been reported in the casualty lists, and these form a comparatively small proportion of the total. None of them have been reported as killed, seven have died, including two retired officers re-employed. The total casualties in the whole service must have been much larger. The number of honours is eighteen, including one Military Cross.

THE AFRICAN MEDICAL SERVICES.

Members of the different African Medical Services have taken part in the long-drawn-out campaigns in German East Africa. The only casualty among them reported has been the death of Captain W. J. Anderson, East African Medical Service, accidentally killed. Many of the younger members of these services are at present serving in the R.A.M.C., with temporary commissions. Any casualties among these officers would be shown among those of the temporary officers of the R.A.M.C.

Three members of the West African Medical Staff were lost at sea in torpedoed ships towards the close of the year.

THE MERCANTILE MARINE.

A large number of liners have been sunk by enemy submarines during the year, and one would have expected that many medical officers of the mercantile marine would have lost their lives in these vessels. But we have only seen two such deaths reported, Dr. J. T. E. Parker, of the *Ivernia*, on January 1st, and Dr. W. F. Alges, of the *California*, on February 7th. Dr. A. R. Steel, of the Admiralty Transport Service, was also lost at sea in the transport *Mendi* on February 28th.

WOMEN DOCTORS.

We should also mention here the deaths of several women doctors on service: Dr. Elsie Inglis, after her return from Serbia; Dr. Isabel Tate, at Malta; Dr. Laura Forster, in Galicia; Dr. Marion Wilson, in France; also Mrs. Harley, killed by a shell at Monastir, in Serbia.

NURSES.

In 1915 no nurses were reported as killed or wounded, but eleven lost their lives in torpedoed hospital ships. None were reported lost in this way in 1916, and none were killed, but five were returned as wounded. In 1917 the casualty returns of the nursing services have been much larger—eight killed, probably in most cases by enemy aircraft; fifteen lost at sea, and sixteen wounded.

HONOURS.

The various honours bestowed on members of the different medical services are shown in Table III. Honours gazetted on January 1st, 1917, are included, but not those of January 1st, 1918. The small number of British honours which has gone to the medical department of the Royal Navy cannot fail to be observed, but we may note

that something has been done to repair this apparent neglect in the New Year Honours List of 1918. On the other hand, a considerable proportion—nearly one-fourth—of the honours granted by foreign governments to medical officers have been received by naval medical officers. These include French, Italian, Belgian, Russian, Serbian, and Japanese decorations. The column headed "miscellaneous" includes a number of orders, of which only a few of each have gone to the medical services—the Royal Victorian Order, the Star of India, the Indian Empire, the Kaisar-i-Hind, the British Empire, etc.; also the Order of British India, and the Indian Order of Merit, bestowed upon Indians only. Honours conferred upon retired officers of the R.A.M.C. and I.M.S. are included along with those on the active list.

The most coveted honour of all, the Victoria Cross, has been granted to only two medical officers during the year, both posthumously. The Cross was conferred on temporary Captain H. Ackroyd and a clasp on Captain N. G. Chavasse, T.F. We believe that a clasp to the V.C. has been given only some four times. It had only once before been bestowed during this war, when temporary Captain Martin-Leake received a clasp to the Cross which he gained in South Africa. Captain Chavasse has been the first and so far the only officer to gain both Cross and clasp during the present war.

Up to the end of 1917, in nearly three and a half years of war, eight Victoria Crosses and two clasps have been bestowed on medical officers. Four of the recipients have fallen in action, the rewards being posthumous. Two were earned in Gallipoli, one in Mesopotamia, the other seven in France. Their distribution among the services has been:

R.A.M.C.—one, Captain H. S. Ranken (killed), November 16th, 1914.

R.A.M.C.(T.F.)—three Crosses and one clasp: Captain J. L. Green (killed), August 5th, 1916; Captain W. B. Allen, October 26th, 1916; Captain N. G. Chavasse, October 26th, 1916, and clasp (killed), September 14th, 1917.

R.A.M.C.(temporary)—two Crosses and a clasp: Captain Martin-Leake, clasp, February 18th, 1915; Lieutenant G. A. Maling, December 18th, 1915, and Captain H. Ackroyd killed, September 6th, 1917.

Canadians—one, Captain F. A. C. Scrimger, June 23rd, 1915.

I.M.S.—one, Captain J. A. Sinton, June, 1915.*

G.C.B.

Another noteworthy honour of the year was the G.C.B. conferred upon Sir Alfred Keogh, Director-General of the Army Medical Service. This is the first occasion on which the Military G.C.B. has ever been given to a medical officer. Sir John McNeill, of the Bombay Medical Service, received the Civil G.C.B. in 1835, but that honour was conferred for services as Minister Plenipotentiary in Persia, long after he had retired from the I.M.S.

* Since the above was written another V.C. has been conferred on a medical officer. Among a number of Crosses gazetted on January 11th, 1918, was one posthumously bestowed upon Captain J. Fox Russell, R.A.M.C.(T.F.), of the Welsh Fusiliers, who was killed on November 6th, 1917.

British Medical Journal.

SATURDAY, FEBRUARY 9TH, 1918.

THE HOME COMMANDS TO-DAY.

IF we take the Army List of July, 1914—and there has not, we believe, been any change in this respect since—we find that there were eight army commands in the United Kingdom. The Scottish and Irish Commands embraced the whole of those countries. One of the English Commands (Aldershot) was a special case, covering a small area, and the London District was confined to the county of London, with certain outlying dépôts. The whole of the rest of England and Wales was divided into four commands—Northern, Western, Eastern, and Southern. The Northern comprised the eastern part of the country from the Tweed to the Wash; the Western consisted of the west of England from the Solway to the Bristol Channel and the whole of Wales; the Eastern Command comprised the eastern part of the country from the Wash to the English Channel. The Southern extended from Warwickshire to the Channel and from Hampshire to the Land's End. In each of these large districts we find a general officer in command, and at his head quarters a deputy director of medical services, with a small medical staff. The head quarters of the Northern Command were at York, of the Western at Chester, of the Eastern in London, and of the Southern at Salisbury; of the Scottish in Edinburgh, and of the Irish in Dublin. It will be seen that the responsibilities of the Deputy Director of Medical Services in all these cases extend over very wide areas. In response to the growing demands for the care, treatment, and restoration of the wounded and sick the medical organization of a command has now attained very large dimensions. In each command is a number of first line general hospitals. There are, in the first place, the Territorial general hospitals; the scheme for these had been carefully laid down by Sir Alfred Keogh in 1907, and he had readily obtained the assistance of the medical profession in working it out. They were all mobilized on the outbreak of the war and they have since been much enlarged, so that in place of the 520 beds they were originally planned to furnish each now provides several thousand. In addition, to meet the need for more first line beds, other large general hospitals have been established in the commands. In the second line we have many auxiliary hospitals, each providing a relatively small number of beds but collectively a very large total. There may be as many as three or four hundred such hospitals scattered through the command. Orthopaedic centres constitute a new element in medical organization; they have already attained large proportions and must continue to grow in importance. These centres also have their dependent auxiliary hospitals. Next may be mentioned the convalescent camps, and lastly the command dépôts, to which recruits or convalescents may be sent for hardening, and military camps of training. In addition, provision must be made for the ordinary medical work in connexion with troops in the command.

The large general military hospitals are officered by practitioners engaged before the war in civil practice. In some cases, however, the commandant of

the hospital is a regular R.A.M.C.—probably a retired officer re-employed; these officers, we regret to say, have not in all cases shown the necessary tact and discretion. Territorial general hospitals, according to the original conception, were to be staffed by civilian practitioners, usually surgeons and physicians of the big civil hospitals in the centre. Before the war there was a skeleton organization, which was to be completed, if and when necessity arose, by civilian physicians and surgeons who received commissions in various ranks *à la suite*—that is to say, their services were available on mobilization. These surgeons and physicians were duly mobilized in and after August, 1914. While they owe a first duty to the military hospitals, they have to carry on also the work of the civilian hospitals and in other ways meet the demands of the civil population. This was the keystone of the original plan. Their numbers have in some areas been greatly reduced owing to the seconding of many members of the staff for service abroad, especially the younger members and those most physically fit. In this way the staffs not only of the military general hospitals but also of the civil hospitals have been depleted, and the amount of work falling upon those who remain, generally senior members of the profession, that is to say, men no longer possessing the resiliency of youth, has been correspondingly increased. Further, it must be noted that the responsibility for inspection of the second line or auxiliary hospitals rests upon the commanding officer and other members of the staff of the general hospital to which they are affiliated. The auxiliary hospitals, as is well known, are staffed usually by practitioners in the district, who give part of their time to this military work, carrying on during the rest of the day the ordinary work for the civilian population.

The custom of the War Office has been to place at the head of this large organization in each command a surgeon-general of the regular A.M.S. It requires no argument to establish that the duties of the officers holding these appointments are of an exceedingly important nature, calling for organizing ability, tact, and a knowledge of civilian medical affairs which can be possessed by few medical officers who have grown grey in the army. It might have been anticipated that if these appointments were to be reserved for regular officers, men of tried capacity, in the full vigour of life, and with minds open to new impressions, ready to receive sympathetically suggestions for handling conditions as to which they must necessarily have had little previous experience, would have been selected. Whether it can be said that this is what has happened we do not propose to discuss, for we desire to avoid any flavour of personal criticism; but the question naturally arises whether, in some instances at least, civilian practitioners who have worked as commissioned officers in war areas for several years and there gained experience not only of army administration, but also of the special circumstances of the immense military forces now on foot, might not wisely have been selected for the office of D.D.M.S. in some of the Home Commands.

This policy has not been pursued. Not only have appointments open to senior officers A.M.S. with the armies abroad, which have been multiplied many times, been kept a close preserve for them, but also those at home. We believe that this policy is mistaken, and that it should be abandoned. We are confident that there are a sufficient number of medical officers not belonging to the regular R.A.M.C., among the senior Territorial medical officers especially many of whom have served for twenty years or more, who

would make highly efficient Deputy Directors of Medical Services, and would carry on the duties of the office to the satisfaction of the War Office and of the civilian practitioners under their jurisdiction.

There is in each command at home at least one consulting surgeon and in some a consulting physician also. When they were appointed, the conception of their duties was that these were purely clinical. They were to visit the first line and second line military hospitals on request and to consult with the staffs of these hospitals on difficult cases. The conception was quite sound so far, but it ignored the fact that it is not possible to divorce clinical medicine and surgery from administration. The consultants soon realized that a large proportion of the cases brought to their notice in consultation assembled themselves into categories, and that for each category there must be a settled policy and often a special organization. Orthopaedic cases afford one instance. The need for a special organization was recognized early, and by accepting civilian guidance and personnel the War Office has been able to organize a system which, though not yet complete, contains all the elements of success, and will confer incalculable benefits on the individual and on the nation, if the Pensions Ministry can be aroused from its lethargy. The numerous cases of neurasthenia and shell shock afford another instance of a class of war patients calling for a special organization. This is now in its infancy and its friends are standing by its cradle watching that the wrong kind of milk may not be put into its bottle, and, indeed, to make sure that it has a cradle of any kind. Fractures, especially of the joints and of the femur, afford another instance; it was only last week that the Army Council summoned up sufficient resolution to direct that these orthopaedic cases should be sent to orthopaedic centres or to hospitals with special departments, where they can be treated by efficient modern methods.

The reason for this digression is that we feel compelled to say that in these matters the civilian profession, including the consultant officers in the commands, have not in all cases received the support they had a right to expect from the Directors of Medical Services. This is in fact to put the matter in the mildest form, for too often, we fear, they have been met by indifference or by perceptible, though perhaps unconscious, obstruction. We do not wish to inculcate individuals who are the victims of a system which seems to have no justification in army regulations or common sense—two terms which no doubt are at bottom synonymous. They have been, by the fortune of war and the customs of the service, placed in positions for which their previous experience has not prepared them.

It may be said that the consultant physicians and surgeons in the commands have been remiss in allowing things to drift, and that thereby other civilian practitioners have been handicapped and their work in caring for the wounded and sick rendered less effective than they would have desired. But on behalf of the consultant officers it may be replied that their duties were not at first very precisely set out; that their authority in administrative matters was uncertain; that their relation to the supreme authority in military matters in the command—the Deputy Director of Medical Services—was ill-determined; and that they had no machinery for collective action. This last deficiency has been made good by the constitution of the consultants council, which must necessarily deal with general problems raising administrative questions, and is in the way to increase its influence on the decisions taken. It would

get along better and faster if in the Deputy Directors of Medical Services of the Home Commands it had to deal with men of its own kidney, men broken to the hard give-and-take of clinical practice, who understand the civilian mind.

VERONAL.

Two cases in which the effects of veronal came under consideration have been heard recently in courts of law. In one the inquiry was as to the cause of the sudden death of General Sir Beauchamp Duff, who, it was stated at the inquest, had suffered from insomnia, which had been aggravated by anxiety due to the references to him in the report of the Mesopotamia Commission. It appeared that he had recently been in the habit of purchasing a bottle containing twenty-five tablets of veronal about once a month. The jury returned a verdict that death resulted from narcotic poison, self-administered for the purpose of procuring sleep, and was due to misadventure. In the other case an insurance company, in resisting a claim under a life policy, asserted that the insured person was in the habit of taking veronal and that this should have been disclosed when the policy was effected.

The points of chief medical interest in these two cases are the dose and the matter of the establishment of a veronal habit. Dr. W. H. Willcox, in a paper he contributed to this JOURNAL in September, 1913 (p. 663), gave 15 grains as the smallest dose of veronal which had proved fatal. A medical witness at the inquest said that he had known a case in which 5 grains had produced a fatal result. This statement, we gather, applied to a particular case of a class probably best included among those mentioned by Dr. Willcox in which the veronal may be regarded as a contributory cause of the death of a patient in a bad state of health, rather than the actual cause. The same witness stated that veronal produced a certain amount of tolerance, but not so much as morphine or other drugs. In the insurance case Sir James Mackenzie, in the course of his evidence, said that there was no such thing as a veronal habit; people did not crave for it as they did for morphine or bromides, but took it only to meet the particular necessity. After recording this view, which, however, is not accepted by all medical authorities, we come to the point that a person may become addicted to the use of veronal, and that in certain conditions of health a dose of 15 grains—that is to say, three of the tablets ordinarily sold—may produce a fatal result. By an Order in Council made some time ago, diethyl barbituric acid and other alkyl, aryl, or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal, or by any other trade name, and all poisonous urethanes and urcides, were included in Part I of the schedule of poisons under the Pharmacy Act. The effect of the order is that veronal and the other allied substances may now be sold only to persons who are either known to the chemist, or are introduced by some one known to him, and that on the occasion of each sale the vendor must at the time of sale and before delivery make the prescribed entry of the sale in his poisons book, to which the signature of the purchaser, and of the person, if any, who introduces him, must be affixed.

The Home Office has issued an official notice to the public in the following terms: "There have been many cases of veronal poisoning in this country, and it is desirable that it should be known that the drug

cannot safely be used except upon the advice of a medical practitioner on each occasion. Many persons are specially susceptible to its action, and fatal poisoning may occur even from small doses of the drug, especially if repeated. The danger is still greater when doses are progressively increased. It is most important, therefore, that veronal and its derivatives and allied substances should only be taken with the knowledge and consent of a medical practitioner, and on his written prescription, and it is advisable that the dispensing of such prescriptions should not be repeated without the written sanction of the medical man."

AN EIGHTEENTH CENTURY "BRITISH MEDICAL JOURNAL."

WE have received from Dr. Selje Bennett a most curious document in connexion with the history of the medical press in this country, and one of peculiar interest to the readers of this journal. The document in question is a prospectus of a medical journal entitled the *British Medical Journal*, to be published by R. Phillips of St. Paul's Churchyard, on February 1st, 1799. The price of the periodical was fixed at two shillings; it was to be continued monthly, in octavo size, containing at least six sheets, and its objects were to give the "earliest information on subjects of Medicine, Surgery, Chemistry, Pharmacy, Botany, and Natural History." Amongst other items of interest, all of them set out in an attractive form in the prospectus, there was to appear in the first number "an accurate description of the real plant and Balm of Gilead; its growth and remarkable properties, for which it has long been celebrated, both as a cosmetic and internal medicine among oriental ladies." It is certainly strange that the name of this journal should have anticipated ours, for there is, of course, no connexion between the two, but stranger is the fact that no trace of this eighteenth century *British Medical Journal* can be discovered. After a search in the British Museum, the Library of the Royal Society of Medicine, the Library of the College of Physicians, and other libraries, we are unable to find a journal corresponding to the prospectus of the *British Medical Journal*, now in the possession of Dr. Selje Bennett. It would appear, therefore, that this journal never went beyond the prospectus stage. It was at least possible that the *London Medical Review and Magazine* or the *Medical and Physical Journal* (both of which appeared in 1799, the date of the prospectus of the *British Medical Journal*) might have been launched under that title, but on reference to those journals no support is given to the supposition. So far as is known, therefore, Dr. Selje Bennett is the happy possessor of a rare and perhaps unique document in connexion with the history of the medical press. Modern editors of medical journals may be well acquainted with the methods by which their journals are made popular, but we think, after reading the prospectus, that the most skilful of them would bow down to this unknown writer, and would admit that medical editors in the eighteenth century were fully equal to those of the twentieth in the art of drawing up an attractive prospectus. R. Phillips, of St. Paul's Churchyard, was a well-known publisher in his day, and made somewhat of a speciality of medical and educational publications.

VITAMINES IN WAR-TIME DIETS.

THE third of the series of public lectures at University College on biological problems was delivered on February 4th by Miss Margaret Hume, Assistant in the Director's Department at the Lister Institute of Preventive Medicine, who dealt with the subject of accessory food factors or vitamins. Antirachitic vitamins were present in butter and cod-liver oil, and therefore in a time of fat shortage like the present it seemed desirable that

milk, butter, and cream should be reserved for children as far as possible, and vegetable margarine of much less certain virtue used by adults. Experiments at the Lister Institute had shown that the embryo of the grain of cereals was much richer in anti-beriberi vitamins even than the cortex; modern processes of overmilling, therefore, left a deficiency to be made up from other sources. The most concentrated depositaries of anti-beriberi vitamins were unmilled cereals, pulses (in which, apparently, the vitamins were uniformly distributed, and not limited largely to the germ, as in cereals), and eggs, including such dried preparations as contained pure egg. Another highly concentrated source was yeast flour. Meat and vegetables contained a moderate amount but not in a concentrated form, while the pulpy parts of fruits were poor in vitamins. They were present in milk in small but sufficient quantity. The keeping power of anti-beriberi vitamins was good, and they withstood cooking at 100°C.; at higher temperatures they were destroyed, and therefore tinned foodstuffs which had undergone a process of superheating were deficient. The antiscorbutic vitamins were much more delicate and elusive. They were most abundant in fresh citrous foods such as oranges and lemons, but commercial lime juice, so far as had been ascertained, had no such value. Cabbage leaves were rich in this factor, and tubers less so. Antiscorbutic vitamins disappeared from kept food. At room temperature they disappeared from foodstuffs within a few weeks or days; with food in cold storage they could be preserved for some months; they disappeared rapidly in the higher temperatures of cooking and sterilization, and diminished even in the pasteurization of milk at temperatures below boiling point. Indian soldiers in the Eastern campaign whose ration was atta (coarsely ground wheat flour) and dhal (any kind of pulse) were perfectly safe against beriberi but not against scurvy, unless the rations were supplemented by fresh vegetables or meat. It was an important fact, however, that these vitamins developed on the germination of seeds, and at the Lister Institute the dhal of the Indian soldier's ration had been germinated until its value in respect of antiscorbutic vitamins after twenty-four hours' soaking and twenty-four hours' germination was almost as good as that of fresh cabbage. Sufficient vitamins to protect against scurvy would be forthcoming, in the absence of other vitamin-containing food, from about 1 lb. of potatoes a day, or a smaller amount of cabbage, or perhaps a single orange.

CEREALS AND FATS.

WE have so frequently criticized the contempt of science displayed by many lay writers upon food problems that our readers are perhaps weary of the subject. The *Times* has, however, just provided a remarkable illustration of our argument. Our contemporary published on February 2nd a letter from Mr. Charles Fisher, who wrote as an authority on agriculture, criticizing the policy of the Food Controller with respect to stock raising. *Inter alia* Mr. Fisher endeavoured to controvert the conclusion of the Royal Society's Food Committee that a pig must consume 7 lb. of barley to produce 1 lb. of pork. Mr. Fisher's argument appears to us invalid. The Committee did not, as we understand them, contend that a pig weighing x pounds must have consumed $7x$ lb. of meal, but that in the ripening of stores into bacon or pork pigs the yield was somewhere in the neighbourhood of 1 lb. for 7 lb.—a very different proposition. This, however, is a matter with which we are not primarily concerned; the really important issue is the attitude of the *Times*. In a leading article commenting on Mr. Fisher's letter, after quietly assuming that Mr. Fisher's arguments are irrefutable, the following proposition is put forward: "Scientific calculations about food are a very untrustworthy guide to practice, because the data on which they are based are quite inadequate to justify the

conclusions drawn from them." The confidence with which this assertion is made goes far to explain much that has been amiss during the past three years, and will, we are afraid, explain much still to be endured. Scientific calculations, it seems, are untrustworthy guides; no doubt we shall in the future, as in the past, substitute for them rhetoric, "stunts," and again rhetoric. The *Times*, with commendable fairness, gave prominence in an early subsequent issue to a closely reasoned letter from Professor Starling, who, after pointing out that the leader writer's aphorism involved a contradiction in terms, asked the question, to which it is to be feared no one can give a satisfactory answer, "When are we in England to learn that science is nothing but practical experience accurately noted, recorded, and classified?" Passing to the particular topic of food supplies, Professor Starling made the following points: When we are faced by an acute food shortage it is idle to discuss large ideals of agricultural policy. The basal foods necessary to maintain the health and efficiency of our population are cereals and fats. Measures tending to increase the availability of the former for human needs must reduce the supplies capable of being appropriated to stock. Since vegetable oils cannot be produced in large amount at home, we must have recourse to animals to manufacture the necessary fat for us. But, since it is evidently more economical of tonnage to import maize-fed bacon from America than feeding stuffs for home-raised pigs, the appropriate course is not, as Mr. Fisher and the *Times* contend, to increase our home production of pork. We do not think that any serious objection to this can be advanced. Whatever may be said of other parts of the Food Controller's policy, his expressed intentions with regard to stock raising seem to us well considered.

TREATMENT OF SYPHILIS.

WITH the introduction of the dispensary system for the treatment of venereal disease in Germany has come a growing demand for uniformity and the use of the procedure which gives the best results. In the pre-salvarsan period the treatment of syphilis with mercury had become more or less standardized. This cannot yet be said of the present day combined treatment with salvarsan and mercury, which gives, apparently, widely different results according to the systems of dosage employed. Thus Hübner,¹ in a survey of the experience gained in the Elberfeld dispensaries and hospitals, concludes that, with the combined treatment, as practised by himself, one course was totally inadequate, and that only by its repetition at certain intervals could permanent results be secured. He re-examined 243 cases of syphilis treated in 1915 and 1916 in the Elberfeld hospital, and found that of the patients who had neglected to seek medical aid after leaving hospital only 10 per cent. were free from symptoms and gave a negative Wassermann reaction. The percentage rose to 33 among those who had undergone at least one supplementary course of treatment after leaving hospital, and was as high as 66 among the patients who had had the benefit of several supplementary courses. Professor Scholtz² of Königsberg has made an emphatic protest against the supplementary treatment as a matter of routine. He regards the above results as exceptionally bad and indicative of faulty dosage, and claims that by his method of combining these drugs he has effected 100 per cent. of cures among his private patients treated for primary syphilis. The results were almost as good among his hospital patients. Among patients treated for secondary syphilis within two years of infection a single course of salvarsan and mercury effected a cure in at least 85 per cent. Scholtz regards as cured patients who for at least two years have shown no clinical or serological sign of syphilis on half-yearly or quarterly examination. Only when his patients showed signs of relapse after the first course did he prescribe a

supplementary course eight to ten weeks after the completion of the first; it was found that half of these relapsing patients required a third course. He states that while he never experienced any serious accident with old salvarsan, although he and his assistants have given over 30,000 injections, several cases of fatal haemorrhagic encephalitis followed the administration of neo-salvarsan, of which more than 20,000 injections had been given. To judge from these two publications German practitioners are still far from unanimous in their views on the salvarsan-mercury treatment of syphilis.

LOCALIZED PNEUMOTHORAX IN PULMONARY TUBERCULOSIS.

IN contrast to the prominence of laboratory methods in clinical medicine, it is a change to find a paper such as that by M. Fishberg,¹ dealing mainly with old-established physical signs. A localized or interlobar pneumothorax frequently occurs in the course of pulmonary tuberculosis and is often overlooked or regarded as a large vomica. The distinction between the two is difficult, but x-ray examination, especially by screening, has made the diagnosis easier, though skiagraphy is not infallible, and may even be misleading. In fact, Fishberg remarks that he has often been confused by skiagraphic reports when they conflicted with the physical signs, and if one method only was available would prefer physical signs. A bright circumscribed area without lung markings and without a surrounding thick, dark shadow, is strongly in favour of a localized pneumothorax; but, if the local pneumothorax is in front with much adherent lung tissue behind, there may be no bright area; and, on the other hand, the walls of a vomica may not cast a shadow, and so what is really a cavity appears like a localized pneumothorax. A vomica may appear as a clear area when empty, and when full of secretion cast a shadow, whereas a localized pneumothorax does not show these changes. Multiple clear areas necessarily point to the presence of cavities in the lung. Fishberg describes with illustrative cases (1) localized pneumothorax running a rapid and fatal course with symptoms of a complete pneumothorax, and (2) latent localized pneumothorax, with sudden onset of more or less severe symptoms which soon abate, so that the patient feels well and the lesion is not recognized. The sudden onset of pain, cyanosis, and dyspnoea of course suggests pneumothorax, and the sudden appearance of signs of a cavity points in the same direction. A localized pneumothorax is as a rule dry and without the adventitious sounds commonly heard over a large cavity. The presence of a large dry cavity, especially when extending into the axilla, should arouse suspicion. Metallic breathing is common in a localized pneumothorax, rare in a cavity. Whispered pectoriloquy is common in localized pneumothorax, rare in vomicae. The percussion note over vomicae is rarely tympanitic, whereas the cracked-pot sound is more frequent over vomicae. The coin sound is exceedingly rare over vomicae, but sometimes present over a localized pneumothorax. Bulging and widening of the intercostal spaces may be noted over local pneumothorax. Displacement of the heart need not occur in association with a localized pneumothorax. Although a consideration of all these points will clear up most of the doubtful cases, there are some in which the diagnosis fails.

THE FATE OF THE CYST DUCT AFTER CHOLECYSTECTOMY.

EISENDRATH AND DUNLAVY² refer to three cases, including one previously published by Floercken, in which after removal of the gall bladder recurrence of the symptoms has been due to dilatation of the cystic duct so as to form a new gall bladder with or without the formation of

¹ *Muench. med. Woch.*, July 10th, 1917.

² *Ibid.*, September 11th, 1917.

¹ *Arch. Int. Med.*, Chicago, 1917, xx, 739-760.

² *Surgery, Gynaec., and Obstet.*, 1918, xxvi, 110-112.

calculi; they therefore urge that in cholecystectomy the entire cystic duct should be removed. The experiments of von Haberer and Clairmont were repeated and the results confirmed, namely, dilatation of the cystic duct after removal of the gall bladder with ligature of the cystic duct close to the gall bladder. It may be pointed out that in congenital absence of the gall bladder the common bile duct has been known to show a compensatory dilatation in part of its course, and that in one such case, recorded by Stone, the common bile and hepatic ducts contained calculi. Mayc-Robson also reported dilatation of part of the common bile duct after cholecystectomy. It would therefore appear that the adoption of Eisendrath and Dunlavy's advice to remove the cystic duct as close as possible to the common duct would be likely to be followed by dilatation of part of the common duct. But probably this would be less prone than dilatation of the cul-de-sac of the cystic duct to be attended by calculus formation and recurrence of symptoms.

THE GUILLOTINE AMPUTATION.

THE so-called guillotine amputation has found a defender in Professor Kausch, who would seem to be consulting surgeon to the Prussian Guards.¹ His argument is that the guillotine operation, or amputation in one plane at the site of injury, is conservative, inasmuch as it results when successful in the preservation of a longer stump than with other methods. He admits that sometimes life may thus be sacrificed, but he holds that it is a greater misfortune that young men should lose a limb unnecessarily than that sometimes one should die from attempts to save it (or a part of it). He does not recommend, nor practise, re-amputation in these cases, but claims to be able to cover the protruding bone and exposed soft parts by vigorous weight extension. By this is to be understood the use of a weight of 10 to 15 kilos (22 to 33 lb.) attached to the skin by strips of twill and mastisol. He gives details of one of his best cases, in which the patient refused reamputation by other surgeons. After four months of Kausch's treatment an excellent result was obtained, judging from the illustrations; but the patient suffered very severely before this happy consummation was reached. Many British surgeons think that a large number of lives have been sacrificed by low guillotine amputations, and we believe that in our armies the operation is not now often done. In considering the pros and cons for amputations at various levels Kausch formulates his conclusions by describing "Wertzonen" or sections of relative values in the several bones of the extremities, and elucidates them by a figure. Unlike most British authorities, and contrary to the experience of limb makers, he estimates the articular ends of the long bones as of the greatest value, but his arguments are unsound, and his conclusions invalid. In the same paper he recommends bone transplantations for prolongation of short stumps of fingers, and also arms and forearms. These, we think, however, are of doubtful practical value, even when aseptic conditions can be obtained. Kausch himself states that at the front he did not see one primarily healed amputation.

THE NEW DIRECTOR-GENERAL I.M.S.

THE post of Director-General of the Indian Medical Service, which has been vacant since the death of Surgeon-General Sir Charles Pardey Lukis, K.C.S.I., on October 21st, 1917, has been filled by the appointment of Surgeon-General William Rice Edwards, C.B., C.M.G. Surgeon-General Edwards was born in 1862 and educated at Clifton and the London Hospital, where he was house-surgeon and house-physician. He graduated M.B.Durh. with honours in 1884, and took the diploma of M.R.C.S. in the same year. He entered the Bengal Medical Service as surgeon on April 1st, 1886, became surgeon-major on April 1st, 1898, lieutenant-colonel on April 1st, 1906, colonel

on May 25th, 1914, and surgeon-general on April 1st, 1915. After two years in military employ and a short spell of civil employ in Bengal he became, in 1890, surgeon on the staff of Lord Roberts when Commander-in-Chief in India. Afterwards he entered the political department, and in April, 1892, was appointed civil surgeon of Quetta, Baluchistan. His services were lent to the War Office in 1900, and when Lord Roberts took the supreme command in South Africa in December, 1899, he chose Major Edwards, as he then was, as his personal surgeon. In South Africa he served in the Cape Colony, the Orange River Colony, and the Transvaal; was present in the actions at Johannesburg (May 29th, 1900), Diamond Hill (June 11th and 12th, 1900), and Belfast (August 26th and 27th, 1900); was mentioned in dispatches, in the *London Gazette* on April 2nd, 1901, and received the Queen's medal with five clasps, and the C.M.G. on November 29th, 1900. After his return to India, in November, 1902, he was appointed residency surgeon of Kashmir, and in December, 1910, chief medical officer of the North-West Frontier Province. On promotion to the administrative grade on May 25th, 1914, he was posted as A.D.M.S. of the Derajat and Bannu Brigades, and on April 1st, 1915, succeeded Surgeon-General G. F. A. Harris as inspector-general of civil hospitals in Bengal. He was made a C.B. on June 22nd, 1914, and appointed an honorary physician to the King on February 18th, 1917.

BRITISH ORTHOPAEDIC ASSOCIATION.

THE inaugural meeting of the newly constituted British Orthopaedic Association was held on February 2nd at Queen Mary's Convalescent Auxiliary Hospital, Roehampton House, London, S.W. The association has been founded on much the same lines as the important American Orthopaedic Association, and, indeed, partly owes its inception to the stimulus given by certain distinguished American orthopaedic surgeons now in Europe. It is confidently expected that the new body, which has a membership composed of working orthopaedic surgeons, and has determined to require a severe test for the admission of future members, will play the leading part in maintaining the dignity of orthopaedic surgery in the British Isles, and in promoting organized scientific and clinical research in this subject. The new association was formally constituted at an executive session on the date mentioned, a constitution and by-laws adopted, and the following officers elected, namely: President, E. Muirhead Little, F.R.C.S., London; Vice-President, Sir Robert Jones, C.B., F.R.C.S., Liverpool; Treasurer, W. E. Bennett, F.R.C.S., Birmingham; Secretary, H. Platt, M.S., F.R.C.S., Manchester. Demonstrations were given by the staff of the Roehampton Limbless Hospital, including one on types of stumps by Mr. Muirhead Little, and a visit was paid to the workshops. Captain T. P. McMurray, R.A.M.C.(T.), demonstrated an artificial leg and temporary peg legs. Mr. E. M. Corner read a paper on nerve bulbs in amputation stumps, which was discussed by Colonel T. H. Openshaw and Messrs. D. M. Aitken, A. S. B. Bankart, W. E. Bennett, W. R. Bristow, R. C. Elmslie, and T. P. McMurray.

REDUCED NUMBER OF PAGES.

THE damage done to machines and paper by the fire at the works in which the BRITISH MEDICAL JOURNAL is printed, to which reference was made last week, again makes it impossible to print the usual number of pages. We must ask all correspondents to bear in mind the difficulties under which the JOURNAL is being produced. It should be added that it will be necessary almost at once, owing to the restrictions about to be enforced by the Paper Commission, permanently to reduce the number of pages in each issue of the JOURNAL, but a full statement on this point will be made shortly.

¹ Bruns's *Kriegschirurgische Hefte der Beiträge zur klinische Chirurgie*. Heft 42. Tübingen: H. Laupp. 1917.

Medical Notes in Parliament.

Army Medical Service: Committee of Inquiry's Report.—We published last week the answer returned by Mr. Macpherson to a question by Major David Davies on January 28th, but were unable to report the result of a further question on the following day, when Major Davies asked (1) whether the Committee appointed to inquire into the organization of the Army Medical Services had concluded its work; (2) whether it had included in its report any recommendations for the more efficient conduct of Royal Army Medical Corps administration in this country as well as in France; and, if not, (3) whether it was proposed to set up another committee to inquire into the condition of affairs and the state of organization of the Army Medical Services in Great Britain. Mr. Macpherson, in reply to the first two parts of the question, referred Major Davies to his answer of the previous day, and said that the answer to the third part of the question was in the negative. Major Davies then asked whether it was not the fact that the Committee was appointed to deal with the whole subject of the reorganization of the Royal Army Medical Corps in this country as well as in France. Mr. Macpherson: No. My hon. and gallant friend will realize, and my hon. friend (Mr. Pringle) to whom I gave the pledge will corroborate me, that it did not refer to that subject at all.

Ministry of Pensions: Director of Medical Services.—In answer to Sir G. Thomas, on January 29th, Sir A. Griffith-Boscawen, Parliamentary Secretary to the Ministry of Pensions, said that the Director of Medical Services to the Ministry of Pensions was entrusted with the administrative control of the Chelsea Medical Board, of the Special Medical Boards in London and the provinces, and of the other medical services of the Ministry, and also acted as adviser in matters of treatment and in the establishment and supervision of institutions for this purpose. The appointment (which was for no specified period) was a whole-time one, carrying a non-pensionable salary of £1,200 a year, the amount to be subject to reconsideration after the war. In the case, however, of the present holder, Sir John Collie, the Treasury had sanctioned the payment of a salary, personal to himself, of £1,500 a year.

Military Rations at Home.—In reply to Major Lane Fox, Mr. Forster said that the scale of rations for all troops serving at home, except those in training or otherwise in preparation for service overseas, and in mobile formation for home defence, had been reduced by about one-third.

INSURANCE AMENDMENT BILL.

Newly Married Women.—The National Health Insurance Bill was taken in Committee and on Report in the House of Lords last week. A matter of interest was Lord Knutsford's amendment to Clause 22, which proposed that an insured woman should be given a benefit of £2 on notifying her approved society of her marriage and going out of insurance through ceasing work. Lord Knutsford's objection was that this would apply insurance money wrongly, and would diminish the advantages of insurance. It had been intimated that one reason why the change was proposed was the difficulty of getting insured women to notify upon marriage. Viscount Sandhurst, for the Government, agreed to fall in with the general wish to abandon the grant on marriage and to rearrange women's insurance on marriage for a limited period after marriage. The proposal was that a married woman ceasing work within one year after marriage is to be considered as having been employed when she has been actually away from work for eight consecutive weeks not due to illness. She is to be insured for sickness benefit at the rate of 5s. per week for one year following employment, subject to the condition that not more than six weeks' benefit in all is to be received during the year. She was also to be insured for a maternity benefit of 30s. for one confinement within two years of the date of marriage. Further, she was to be entitled to medical benefits and sanatorium benefits to the end of the calendar year next after that following marriage. The new clause was accepted by Lord Knutsford and agreed to without division. Lord Knutsford said it was a very good solution that every woman who married and ceased employment should have five shillings a week, limited to six weeks, and that she should have 30s. maternity benefit for her first child born within the first two years of her marriage.

Illness due to Misconduct.—Lord Sydenham moved a new subsection, the object of which was to lay down that, notwithstanding any provision to the contrary in any rule of an approved society, an insured person suffering from venereal disease should not, on the ground that this disease might have been due to misconduct, be deprived of any sickness or disablement benefit to which otherwise he or she would have been entitled. Lord Sydenham said that the effect of the misconduct rule had been to cause concealment of disease, thereby preventing treatment being given at the proper time, and increasing the danger to the public afterwards. The economical effect upon the insurance societies had been that they were burdened in later years with the later effects of these diseases. Viscount Sandhurst, for the Government, said that it was thought that the object of the amendment was more likely to be gained, and without friction, not by a clause in the Acts, but by leaving it to be done in the rules of the societies; but he had agreed to submit an amendment which would absolve societies from holding certain meetings before making the rules. The Commissioners proposed to issue a circular to the societies, many of which acknowledged the need for the change, indicating the views put forward by Lord Sydenham. The amendment was then withdrawn, and the clause was amended as Lord Sandhurst had suggested.

Venereal Disease in the Army.—Mr. Peto asked Mr. Macpherson whether his attention had been called to the War Office letter to general officers commanding, dated March 18th, 1916, which stated that the Army Council could not accept suggestions made with regard to prevention which would imply the adoption of any system of prophylaxis which might be said to afford opportunities for unrestrained vice; whether this deterred army medical officers from taking steps to prevent the spread of venereal disease in the army; and whether the Army Council would now withdraw any restriction which prevented effective measures from being taken to avoid the waste of man power in the army from this cause. Mr. Macpherson regretted that he could add nothing at present to the answers he had given on January 22nd last. Mr. Peto asked Mr. Macpherson to give some idea, if not accurate figures, of the number of men who passed through hospital suffering from venereal disease in a single year, and who were at any one time incapacitated from this cause. Mr. Macpherson replied that he could not give definite figures. He did not think that the effect of the letter was to prevent medical officers from taking every possible step to prevent venereal diseases.

Representation of the University of Wales.—During consideration in the House of Commons of the Lords' amendment to the Franchise Bill, Mr. Ellis Griffith carried an amendment to give the University of Wales a separate representative. Under the original proposal it was one of a group of universities to return two members.

Committee on the Blind.—Sir Watson Cheyne asked whether the President of the Local Government Board had considered the question of adding one or more ophthalmic surgeons to his Committee on the Care of the Blind. Mr. Hayes Fisher replied that in view of the great demand upon the time of ophthalmic surgeons it appeared that their advice and assistance could be most conveniently secured otherwise than by nomination of a representative upon the Advisory Committee, much of the time of which would be occupied with purely administrative problems. He was, however, willing to invite an ophthalmic surgeon to serve on the Committee if it were desired, and was communicating with the Royal Society of Medicine on the matter.

Report on Army Medical Service in France.—In reply to Major David Davies, Mr. Macpherson said that a copy of the report of the inquiry into the Army Medical Services in France had been forwarded to the Ministry of National Service to assist the Ministry in its function of co-ordinating military and civilian demands upon the medical man power of the country.

Air Force Medical Service.—Major Baird has stated in reply to questions that the arrangements for the medical care of the air force are still under consideration. He anticipated, however, that the matter would be settled at a very early date.

THE specialists in children's diseases in Bogotá have formed a paediatric society.

PROFESSOR VITTORIO ASCOLI, the successor of the late Guido Baccelli, in taking possession of his chair, delivered an inaugural address in the great hall of the Institute of Clinical Medicine, Rome.

THE Edward L. Trudeau Tuberculosis Sanatorium, which was formally opened in Paris on Christmas day, is the first tuberculosis hospital in France created wholly by the American Red Cross. It has only 8 beds at present, but it is hoped to increase the number to 1,200 within the next year.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

LIEUTENANT P. A. WEDGWOOD, R.A.M.C.

Lieutenant Percy Ashworth Wedgwood, R.A.M.C., was reported as having died on service, in the casualty list published on February 5th. He was educated in Edinburgh, at the University and Royal College of Surgeons School, and took the Scottish triple qualification in 1898. After serving as surgeon of the ss. *Derbyshire*, he went into practice at Kirby Underdale, Yorkshire. He had only recently joined the R.A.M.C., and was attached to the Yeomanry.

Wounded.

Captain H. A. Cochrane, Canadian A.M.C.

DEATHS AMONG SONS OF MEDICAL MEN.

Buss, Hilary, Second Lieutenant Royal Flying Corps, son of the late Dr. Laurence Buss, killed in an aeroplane accident in Lincolnshire on January 21st.

Collier, Martin Huntley, Lieutenant R.N., lost at sea on January 19th, aged 25, younger son of Lieut.-Colonel William Collier, R.A.M.C., of Oxford, President of the British Medical Association in 1904. He entered the navy in 1904, and became lieutenant in 1913. He was a fine athlete, and made a reputation in Rugby football and in boxing both at Osborne and at Dartmouth. He played Rugby for the navy, the United Services, and the South, and won the officers' championship in the light-heavy class in 1914.

Scott, James Garnett, Lieutenant R.N.V.R., attached Royal Air Service, only son of the late Dr. W. M. Scott, died suddenly on January 25th. His commission as lieutenant was dated January, 1916.)

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette*, issued on February 4th, contains a further list of rewards for gallantry and distinguished service in the field. The acts of gallantry for which the decorations have been awarded will be announced in the *London Gazette* as early as practicable. The list includes the following medical officers, all of whom belong to the R.A.M.C. unless otherwise indicated:

Bar to the Distinguished Service Order.

Major (temporary Lieut.-Colonel) A. C. Osburn (D.S.O. gazetted June 3rd, 1916).

Distinguished Service Order.

Major (temporary Lieut.-Colonel) C. A. A. Stidson.
Temporary Captain F. F. Carr-Harris.

Bar to the Military Cross.

Captains: C. D. S. Agassiz (M.C. gazetted September 26th, 1917); E. A. C. Fazan (M.C. gazetted January 14th, 1916); S. McCausland (M.C. gazetted July 26th, 1917); J. S. Wallace (M.C. gazetted July 26th, 1917).

Temporary Captains: A. J. Blake (M.C. gazetted September 22nd, 1916); J. W. Macfarlane (M.C. gazetted July 26th, 1917).

Military Cross.

Captain (temporary Major) J. D. Piddes.

Captains: R. V. C. Ash, A. J. Beveridge (S.R.), J. H. Blackburn, R. C. Brewster, N.Z.M.C., E. Douglas, C.A.M.C., J. H. P. Fraser, P. J. Gaffikin (S.R.), A. D. Irvine, C.A.M.C., G. L. Jepson, C.A.M.C., J. G. MacNeill, C.A.M.C., G. Morris (S.R.), H. D. Pickles, J. A. Pridham (S.R.), W. Robertson, W. H. Secord, C.A.M.C., W. E. Sinclair, C.A.M.C., A. P. Thomson, D. L. Wall, J. A. Young, J. C. Young (S.R.).

Temporary Captains: J. V. Cope, D. McD. Dickson, H. B. German, F. A. Grange, E. A. T. Green, J. P. Jones, F. B. Julian, A. G. Maitland-Jones, J. Mannel, D. J. McAfee, F. B. McCarter, J. A. Montgomery, L. M. Rowlette, D.S.O., C. Russell, R. Rutherford, B. H. Swift, G. D. K. Waldron.

Lieutenant (temporary Captain) W. W. MacNaught.

Lieutenants: S. Dutt, I.M.S., J. Marshall (S.R.).

Temporary Lieutenants: A. C. Hallows, E. E. Owens, D. A. H. Moses.

The Military Cross is also awarded to one sergeant-major of the R.A.M.C., while the Military Medal is bestowed upon 31 N.C.O.'s and 76 privates of the R.A.M.C., A.A.M.C., and C.A.M.C.

NOTES.

COLONEL T. H. J. C. GOODWIN, C.M.G., D.S.O., A.M.S., who is about to succeed Sir Alfred Keogh as acting director-general of the Army Medical Service, has been gazetted Surgeon-General.

The silver medal for saving life at sea has been awarded to Captain William L. Cockcroft, R.A.M.C., in recognition of his services on the occasion of the loss of H.M. transport *Royal Edward* in the Aegean Sea on August 13th, 1915.

A special Supplement to the *London Gazette* issued on January 29th announces that the Royal Red Cross decoration had been conferred upon forty-one ladies in recognition of their valuable nursing services.

AMERICA IN THE WAR.

In August, 1917, a board was established to collect materials for a medical and surgical history of the American participation in the war. The members are Colonel Champe C. McCulloch, librarian of the Surgeon-General's library; Major Fielding H. Garrison, formerly assistant librarian, and Major John S. Fulton, professor of State Medicine in the University of Maryland. In addition to an introductory narrative of the events of the war in their bearing upon military medicine, the individual reports of division surgeons, directors of base hospitals, and other medical officers at the front, will be published and lists of all medical officers on active duty in the war. The rest of the work will consist of four sections—statistical, in which all data will be interpreted by modern mathematical methods (Major Fylton); clinical medicine, including neurological cases; surgery, including analysis of cases, treatment of wounds, etc.; and sanitation, prophylaxis, food, water supply, etc.

England and Wales.

NOTIFICATION OF INFECTIOUS DISEASE.

THE Local Government Board has issued an order prescribing a uniform form of certificate or notification by medical practitioners for all notifiable infectious diseases. A separate form is prescribed for use in the metropolis, in view of the specific additional information required under the provisions of the Public Health (London) Act, 1891. In both forms provision is made for the additional particulars required in the case of tuberculosis, ophthalmia neonatorum, and measles or German measles, under the regulations relating to those diseases. The order authorizes the transmission of all certificates or notifications to medical officers of health by halfpenny post instead of letter post. The order relates exclusively to certificates of notification by medical practitioners, and does not affect the duties of certified midwives in suspected cases of ophthalmia neonatorum. The schedules to the order indicate that the Local Government Board is bent on getting value for its shilling.

THE LOCAL GOVERNMENT BOARD AND THE MINISTRY OF HEALTH.

On January 23rd, at the Royal Institute of Public Health, Dr. E. W. Hope, of Liverpool, opened a discussion on the proposed Ministry of Health. Sir Horace Munro, K.C.B., Permanent Secretary to the Local Government Board, who was in the chair, said that fifty years ago the whole question of public health was considered by a Sanitary Commission, and one of its recommendations was that the administration of the laws relating to public health should be presided over by one Minister acting as a central authority. It was in pursuance of that recommendation and of certain other proposals that the Local Government Board was set up to be the ministry of health. The country could look back with very great satisfaction on the progress in health matters since then. The total death-rate had declined by more than one-third, and infantile mortality by more than one-fourth. The present demand for a Ministry of Health had arisen because the State now took a wider view of its responsibilities in relation not only to environment, but to the health of the individual, and this had led to a fresh demand for co-ordination and centralization. The Local Government Board looked forward keenly to the prospect thus opened up. Dr. E. W. Hope said that civil sanitary administrators had been able to render services of the first importance to the naval and military forces, and what had been done in this direction had awakened the public to the need for an improvement in the public health service of the country. Each Government department had had its own independent health branch, and municipalities had worked under

legislative provisions intended to have only a local application, although in many instances, after the measures had been tested in the localities, they had been applied over a wider area. He mentioned in this connexion regulations dealing with housing, town planning, milk supply, assistance to midwives, treatment of ophthalmia neonatorum, and the provision of food for infants. Most of the great sanitary measures from which the country had benefited in the past had originated from the health committees and sanitary authorities of the great centres of population, whose functions dealt with the whole of large units of population and were not sectional in the same sense as those of the various Government departments. Some at least of the Government departments, including the Board of Education, and most conspicuously the Local Government Board, had made independent developments in prevention, not only amplifying the best results of local effort, but initiating useful legislation on preventive lines. The essential thing at present was unification of control at the centre, and the Local Government Board was clearly the body from which the Ministry of Health should emerge. A co-ordination of the health activities of all the other Government departments concerned could be assured by the establishment of an advisory committee upon which representatives of each department would sit, while discharging the same functions as to their respective boards as they discharged now. Dr. Hope concluded by saying that it might be thought he had laid undue stress upon the prevention of sickness and disease, and not enough upon the treatment of it. The curative aspects did undoubtedly link up at some points with the preventive aspects, but, broadly speaking, the former involved a different set of considerations, and an immense amount of work had to be done on the preventive side pure and simple, enough to engage the first energies of a Health Ministry. Sir Francis Champneys expressed the hope that under any arrangement which was made by the Ministry of Health it would be remembered that private midwives were a necessity. The mothers of the poorer class insisted on them, and, while a system of municipal midwifery might perform useful functions, it would not displace the private midwife, who was valued by the mother or prospective mother as a confidant. Sir Robert Morant said that he often found it necessary to remind people that the establishment of a Ministry of Health as such meant the setting up of a central department, and therefore need not involve a large measure, nor of necessity touch local services at all from the legislative point of view. The Maternity Bill might be regarded as supplementary.

Ireland.

POOR LAW MEDICAL OFFICERS' SALARIES.

ARISING out of recent letters in the daily press by the Irish Medical Secretary and other medical correspondents regarding the position of the profession in Ireland, the *Irish Independent* in an editorial says: It may seem strange that some of the boards of guardians most eager to vote increases of salary to their workhouse officials are the most reluctant to grant any increase to the medical officers in their service. During the year ending September 30th, 1916, the salaries and rations of Poor Law officers were increased by £10,270, and, as the ratepayers will have reason to know, by a much larger sum last year. The increases of salaries granted to dispensary medical officers during the year ended March 31st, 1917, was £911. There are 812 dispensary doctors in Ireland, so that the increase in salary given them averaged the munificent sum of £1 2s. 6d. per head. And all this probably was accounted for by some unious adopting the approved scales of remuneration for medical officers sanctioned by the Local Government Board several years ago. Thus it may safely be said that while the workhouse officials, as a rule, have received very substantial increases of salary or war bonuses to enable them to meet the increased cost of living, the dispensary doctors are left as they were before the war. Some, at least, of these pre-war salaries cannot be regarded as adequate when one finds one dispensary doctor paid £80, several others £90, and a good many £100 to £120 a year. This is scarcely fair treatment

for men who have had to spend five or six years qualifying for their profession and are now entrusted with the medical care of the sick poor, whom they have to attend at any hour of the day or night.

THE IRISH LOCAL GOVERNMENT BOARD.

The report of the Local Government Board for the year ended March last states in connexion with the distribution of the sanatorium grant: The total issues out of the Irish portion of the sanatorium grant to March 31st, 1917, amounted to £54,206 19s. 2d. The suspension by the Treasury of further capital expenditure from the sanatorium grant in respect of building new sanatoriums, and, save in special circumstances, of dispensaries, still remains in force. The considerable progress made by the county and county borough councils with the arrangements for the detection and treatment of persons suffering from tuberculosis in their areas is noted with satisfaction but it is pointed out that the more important question of prevention has not received the full attention it deserves. During the past year the Board has been called upon to deal with a larger number of soldiers suffering from tuberculosis than at any similar period since the beginning of the war.

Correspondence.

EMETINE BISMUTH IODIDE IN THE TREATMENT OF AMOEBIC DYSENTERY.

SIR,—Captain A. C. Lambert, in his paper on "Amoebic dysentery and its treatment by emetine bismuth iodide," published in the *JOURNAL*, January 26th, 1918, states in his conclusions that this drug "cannot be considered in the light of a substitute for emetine (by the needle), as attempts to treat acute cases with it alone ended in failure, until emetine was used in addition." Though granting that emetine bismuth iodide does not appear to act so beneficially in acute cases as in the chronic carrier type of case, yet it can cure acute cases completely in some instances. I have just written a paper—which will appear in the *Transactions* of the Society of Tropical Medicine and Hygiene for February, 1918—on the treatment of acute and subacute cases of amoebic dysentery by emetine bismuth iodide. Out of a series of three acute cases two were completely cured. I have used the double method described by Captain Lambert, and succeeded in curing by it a subacute case which had resisted emetine bismuth iodide alone, and it is quite possible that it will eventually turn out to be the best method of dealing with acute cases. For carrier cases (in white people) emetine bismuth iodide is far in advance of emetine by the needle, and Captain Lambert's paper now brings out the interesting fact that this applies equally to natives of India. One rather unfortunate point in the paper under discussion is that 2 grain doses were, as a rule, given, either once or twice daily. As 3 grains daily (generally in one dose) has been, more or less, considered the standard in the work done in England, it would certainly have rendered accurate comparisons more easy if a similar dosage had been adopted in Mesopotamia.—I am, etc.,

London, W., Jan. 26th.

GEORGE C. LOW, M.D.,
Temp. Capt. I.M.S.

THE PULSE PRESSURE TEST BEFORE OPERATIONS.

SIR,—Sir James Mackenzie's observation, "Beyond supplying the force that causes the blood pressure, the heart takes little part in the variations that occur," is perfectly sound and most important, and it is sad that Sir James Barr cannot grasp its truth.

One of the greatest stumbling-blocks in the way of progress is the imperfect investigation of primary causes. Sir James Mackenzie rightly remarks: "The factors concerned in regulating the changes in blood pressure are so obscure that observations drawn from them are little better than guesswork," and it is our business to remove this obscurity, and then perhaps we may in time upset the tradition that the heart is responsible for variations in blood pressure instead of being simply the mechanical

pump which is under the control of various determining forces. We may then, perhaps, see fewer cases of vascular disturbance which have been diagnosed as heart disease, but in which the heart is in reality merely the long-suffering, unwilling agent.—I am, etc.,

London, W., Jan. 29th.

ALEXANDER FRANCIS.

SIR.—I suppose every anaesthetist will join in Dr. Blomfield's welcome (BRITISH MEDICAL JOURNAL, February 2nd, p. 161) to Sir James Mackenzie's reference (BRITISH MEDICAL JOURNAL, January 19th, p. 101) to the "bogey so often raised about the heart being unable to stand anaesthetics," and will agree that the greater number of those about whom one is warned beforehand as having "a weak heart" are found to have valvular lesions well compensated, or more often some unimportant "functional" disorder.

I would, however, make this reservation, that it by no means follows that a heart which "can stand anaesthetics" (of course properly selected and properly given) can stand the reflex disturbances of its action, and the variations in blood pressure, which accompany an operation under an anaesthetic. These are often ignored, or assumed to be included in the statement.

During recent years it has been conclusively shown, both by observation of patients and by experiments in laboratories, that general anaesthetics do not altogether block nervous currents from the site of operation (being in this respect inferior to spinal and local analgesics) and that disturbances of the respiration and circulation (perhaps of other functions) continually occur during every operation. They vary in extent and importance with the nature of the operation, and the condition of the patient, but as a possible danger should always be taken into account. As an instance:

I was asked to anaesthetize for suprapubic prostatectomy a man aged 65, but looking much older, of sedentary habits, feeble, edentulous, and dyspeptic, with lateral curvature of the spine and tachycardia, his pulse being uncountable by the usual method. I was told by the operator that an eminent physician had advised that his tachycardia was "neurotic," and that he could "take an anaesthetic quite well." Knowing that enucleation of the prostate is attended by reflex disturbances which as a rule include a sudden and considerable rise in blood pressure, I came to the conclusion that, supposing the nerves and muscles of his heart to be as sensitive and weak as the rest of him, if I were to rely upon general anaesthesia alone, he (requiring a deep degree) might die of overdose on the one hand or of shock on the other, and that if I relied upon spinal analgesia alone he might (like many a one in pre-anaesthetic days) die of sheer fright. So I gave him just enough anaesthetic to make him unconscious, and then an intrathecal injection. He needed no anaesthetic during the operation, which was done without any appreciable disturbance of pulse or breathing, and at the close he was regaining consciousness, and his pulse was much better than before.

Fortunately, in this instance it was possible to protect effectively the vital centres (and consequently the heart) from disturbance, but it need hardly be said that during some operations this would be difficult or impossible—and I doubt whether the physician who saw him was aware that such a problem must be faced.

I have told the story, because it seems to bear upon what some of us have been urging for years, namely, that when there is doubt, an anaesthetist should be consulted beforehand, as well as a physician, or even in preference to the latter.—I am, etc.,

London, N.W., Feb. 2nd.

J. D. MORTIMER.

THE VALUE OF THE SANATORIUM.

SIR,—I have followed with great interest the letters in the JOURNAL as to the value of sanatorium treatment. There seems to be almost a consensus of opinion as to the importance to be ascribed to environmental factors in deciding the success or failure of this method after the patient leaves the institution. They chiefly determine the event of a fresh attack. They are equally important in bringing about the first illness.

May I be allowed to call attention to a point which seems to me to be the foundation of any logical study of these questions? It is this—that we must draw a strict line between the consideration of treatment and of prevention in this disease. Sir Arthur Newsholme hinted at the essential differences between tuberculosis and the acute infections in his recent report.

All treatment is in a sense preventive. Fractures are

treated to prevent further disasters. By treatment (therapy) in infectious diseases we attempt to restore vital resistance, relative immunity, what you will so long as we all mean the same thing. By prevention we mean its maintenance. We cannot treat a case till we have failed to prevent. We are to a certain extent, I fear, still limited in our conceptions by the first flush of our knowledge of the tubercle bacillus, and not sufficiently alive to such work as Sanarelli's paper at the Rome Congress nor to the importance of such demographical studies as have been made from the material given to us by our Government departments. Sanarelli has, I think, shown that tubercularization is our chief safeguard, and the cause of the fall in the death-rate. I need not go into parallels. In prevention our object must be to secure that tubercularization, which seems to be unavoidable, and is probably better so, is accompanied by the maintenance of vital resistance.

As I have written in various places since 1903, the sanatorium is only an object lesson and a school of hygienic living specially adapted, and demonstrates how we may restore resistance when it is temporarily damaged, and, incidentally, how we fail to do so when it is absent or destroyed.

As showing the value of early diagnosis I attach little importance to those sanatorium statistics proving that more favourable results occur as a consequence of early selection, nor to the demands for earlier diagnosis, whether by laboratory, radiographic, or physical examination, to secure still better results. We must view this question from all sides, and the statements made by Brouardel at the London Congress in 1901 as to the universality of the infection and the disease have been abundantly corroborated since, on the living and the dead. But we still do not know the recovery rates of the various so-called stages or groups of cases except of such as have been diagnosed, and treated in institutions. Admittedly the best results will be obtained among "early" cases.

It is more important and more difficult to form an opinion as to the probable effect of the declared infection, in any stage, on the human organism before us than to make an early diagnosis. This is not to be easily ascertained by "expert" examination before treatment, but only by prolonged observation under treatment, which should be accompanied by all the hygienic rules of the game. That these are best seen at the sanatorium goes without saying.

I venture to ask permission to call attention to the enormous importance of the duties of tuberculosis officers other than their merely clinical functions, especially in studying the factors of loss of resistance, and every factor other than infection which causes a high morbidity from tuberculosis in the populations committed to their charge. The potential value of the work of the general practitioner clinically is often overlooked, or sometimes even disparaged, and valuable time is lost while his work is being done for him.—I am, etc.,

London, W., Jan. 19th.

THOMAS D. LISTER.

ACUTE YELLOW ATROPHY IN SYPHILIS.

SIR,—In your issue of January 19th, p. 76, Dr. Stuart McDonald has brought forward a subject which requires the earnest attention of all syphilologists. Between the years 1906 and 1914 I saw only five cases of jaundice and one of yellow atrophy in syphilitics who had not been treated. These six cases occurred early in the generalization stage, before the rash had even fully developed. The case of acute yellow atrophy was preceded for some weeks by jaundice. Since 1914, instead of seeing no further cases in untreated subjects, I have come across 21 cases of jaundice and 8 of acute yellow atrophy in patients who had been treated with salvarsan. In the 29 cases the hepatic trouble for the most part occurred within eight weeks after the last injection of salvarsan. All the cases of acute yellow atrophy started as such, and terminated fatally within five days.

I cannot help thinking that these are cases of arsenical poisoning, for the following reasons: The commonest symptom of arsenical intoxication is dermatitis, which not infrequently ends fatally with signs and symptoms of bronchopneumonia. *Post-mortem* sections of the liver and kidneys often showed commencing parenchymatous degeneration. Arsenic may attack the kidneys primarily, and the patient dies of uraemia. *Post-mortem* necrosis

and profound fatty degeneration of the parenchymatous cells are evident, akin to the necrosis and degeneration of the parenchymatous liver cells in acute yellow atrophy. In the primary hepatic and renal involvement the spleen is usually enlarged and soft, and there may also be degeneration of the cardiac muscle fibres. All these cases usually occur before the eighth week if the injections have been given intravenously, and sometimes as late as the eighteenth month if the salvarsan has been injected intramuscularly. I have been able to group the large number of cases of arsenical poisoning I have come across since the war started into four classes:

1. Those in which the skin is primarily involved; death from bronchopneumonia. *Post mortem*—slight parenchymatous degeneration of the liver and kidney cells.

2. Those in which the liver is primarily involved; death from acute yellow atrophy. *Post mortem*—necrosis and profound degeneration of the liver cells with a lesser degree of the kidney cells.

3. Those in which the kidney is primarily involved; death from uraemia. *Post mortem*—necrosis and profound degeneration of the renal cells, with a much lesser degree of the liver cells.

4. Those in which the brain is primarily involved; death from acute encephalitis. *Post mortem*—profound degeneration of the cortical brain cells, with a lesser degree especially of the kidney cells.

In my opinion arsenic acts as a toxic agent by increasing the hydrogen ion concentration of the blood, a statement supported by the fact that chloroform, which has a similar action, may precipitate symptoms of acute arsenical intoxication.¹ If this view be correct, then arsenic should be able to be prevented from causing toxic symptoms by the introduction of a drug which increases the hydroxyl ion concentration of the blood. Sulphur has this action, and this is the reason why I have so strongly advocated the use of intramine (di-ortho-amino-thio-benzene) in all cases in which arsenic, and even mercury, was being used.

Since I have used intramine I have given up to date over 6,000 injections, and in none of my cases has arsenical poisoning occurred. Moreover, intramine is the only drug capable of curing arsenical dermatitis, and in three cases of jaundice I have seen it do good.

Dr. McDonald's finding of organisms of the coli-typhoid group can, I think, be easily explained. In many cases of arsenical dermatitis a staphylococcal infection in the form of boils may develop two or three weeks after the onset of the rash. Doubtless this infection is of a secondary nature due to a lowered resistance, and can in no wise be regarded as an etiological factor. As staphylococci complicate a skin case, it is only reasonable to suppose that it would be coli organisms which would complicate a liver case, therefore the incidence of the above finding is rather to be interpreted as a result than a cause. There is so much disparity between the number of cases of hepatic trouble which occur in untreated and treated cases, that I am led to the view that the great increase is directly due to the toxic action of arsenic. It is doubtless due to a reason of fear that many other cases have not seen their way into print, because every possible excuse is made to avoid labelling deaths after salvarsan as being due to arsenic, therefore Professor McDonald should be congratulated on opening up such an important subject. I cannot agree with him that there is no evidence that the salvarsan has materially altered in the last three years, because in my experience the alteration has been most marked, a point to which I have repeatedly drawn attention since the outbreak of the war.—I am, etc.,

London, W., Jan. 20th.

J. E. R. McDONAGH.

THE CAUSATION OF SEX IN MAN.

SIR,—The following case may be of interest: Mrs. —, aged 25, was delivered of twins, one being male and the other female, on January 12th, 1918. In April, 1916, Dr. Hellier of Leeds had performed a left salpingo-oophorectomy and ventral fixation. It might be of interest also to state that the ventral fixation caused such a doubling over of the uterus as to form a separate pouch, in which the second fetus was tightly held. This pouch lay in front of the lower segment of the uterus, which had held the first-born fetus. Delivery required considerable manipulation.—I am, etc.,

Normanton, Jan. 1st.

N. STUART TWIST.

¹ Practitioner, January, 1918.

THE INCREASE OF CAPITATION AND PRIVATE FEES.

SIR,—These two points are now being discussed, and in my opinion, so far as rural practitioners are concerned, should be considered together. Have we any right to expect private patients to pay higher fees if we are still willing to receive the totally inadequate remuneration under the Insurance Act?

I have on several occasions quoted figures based on my own personal experience. During the past year records have not been insisted upon, so I cannot make any exact calculation, but I have little hesitation in saying that, under the Insurance Act, my own remuneration for dispensing barely covers the cost of drugs, bottles, etc., and that, after allowing for cost of locomotion, etc., the fee for a consultation or visit must be reckoned in coppers and not shillings. My experience may be exceptional, but can scarcely be unique.

Can any one point to any other body of men who have not been compensated by war bonus or other means for necessarily increased expenses in carrying out a contract owing to the war?

When we have demanded and received extra remuneration under the Insurance Act to cover the extra cost, and when we have been paid on the full number on our lists, then let us consider the raising of fees all round.—I am, etc.,

West End, Hants, Feb. 4th.

C. H. POWERS.

Obituary.

JOHN McCRAE, M.D. TORONTO.

LIEUT.-COLONEL C.A.M.C.; CONSULTING PHYSICIAN, B.E.F., FRANCE; LATE SECOND IN COMMAND (McGILL UNIVERSITY), CANADIAN GENERAL HOSPITAL.

LIEUT.-COLONEL JOHN McCRAE, the distinguished Canadian physician and author, died with painful suddenness on January 28th, of pneumonia. On January 23rd, the day upon which his illness first showed itself, the order came through for him to join one of the armies as consulting physician.

He was the second son of Lieut.-Colonel David McCrae, and was born at Guelph, Ontario, in November, 1872. He was educated at Guelph and at the University of Toronto, where he graduated B.A. in 1894, M.B. in 1898, and M.D. in 1910. In 1899 he was appointed Governors' Fellow in Pathology, McGill University, Montreal, becoming later lecturer in pathology, and then in clinical medicine, at the same university. He studied abroad under Marchand and others. He was assistant physician at the Royal Victoria Hospital, Montreal, and physician to the Alexandra Hospital for Infectious Diseases.

An active and rapid worker, he was co-author with Professor Adami of a well-known textbook of pathology, of the article "Oesophagus" and yet other articles in the *System of Medicine* by Sir William Osler and Dr. Thomas McCrae, his elder brother, and contributed many articles on pathology and clinical medicine to the medical journals. He was on active service as a combatant officer in South Africa during the Boer war, and went overseas with the first Canadian contingent in October, 1914, as medical officer to the 1st Brigade, Canadian Field Artillery. When the McGill University Hospital unit was formed, in the spring of 1915, he was appointed lieutenant-colonel in charge of the medical division, joining that unit when it reached France in the summer of that year. With it he remained until his death, serving with the utmost efficiency and loyalty. The paragraphs which follow, by Colonel Elder, O.C. McGill University Canadian General Hospital, and by Lieut.-Colonel J. G. Adami, with whom he was so long associated, will indicate the position he held and the influence he wielded. He was unmarried.

Lieut.-Colonel ADAMI writes:

There have been few finer characters, or men of richer and more varied endowment in the Imperial Medical Service than John McCrae. First and foremost he was a soldier, sprung from old Galloway fighting stock. Seven out of the eight McCraes who find mention in the last issue of "Who's Who" are soldiers. His father, Colonel David McCrae, who had been a noted breeder of Galloway cattle,

when he had passed seventy came again to the colours, raised and brought a battery to England, and bore it hardly that he was not permitted to take it to Flanders. When the Boer war opened John McCrae himself, a junior militia officer in the 16th (Howitzer) Battery of his native town, Guelph, although by now a graduate of medicine and just embarked upon his career in Montreal, found the call too strong for him, and at the first opportunity went to South Africa as a lieutenant in the Canadian Artillery. There he was present at Belfast, Lydenburg, and several other engagements, and gained the Queen's medal with three clasps. In 1902 he gained his majority and was given command of his original battery. But for the fact that he was on his way to England when the great war opened, he would have served under his old chief in South Africa, Colonel (now Brigadier-General) E. W. B. Morrison, D.S.O., C.M.G., as a combatant officer in the First Canadian Field Artillery. Rather than be left behind he had to satisfy himself by accompanying the brigade as medical officer, in the hope that, should a vacancy occur, he might be given a battery. In this position his partiality for observation posts caused some little trouble. He was with the brigade all through that critical day in April, 1915, when, along the Yser Canal, north of Ypres, the scant line of Canadian guns, with not too abundant ammunition, alone intervened between the German hosts and Calais and Boulogne.

The straining at the leash to take an active part when compelled to be merely an onlooker told upon him, and when the call came to join No. — (McGill University) Canadian General Hospital as head of the medical service, he recognized, although with a heavy heart, that his duty lay with his colleagues who formed the unit.

For if he was a soldier by birth, medicine has been his life's work, and for sixteen years he had been associated with the staff of McGill Medical Faculty, first as pathologist, later as lecturer in clinical medicine. In his chosen profession the place he had gained is indicated by the fact that he was one of the eight or so Canadian members out of the six score who constitute that most select body, the Association of American Physicians. Apart from his great personal charm he was admirably equipped to become a leader in the profession. Although belonging to the rival university I willingly admit that in the late eighties and early nineties, for those capable of taking advantage thereof and electing to pursue further studies elsewhere after graduation, the University of Toronto afforded the finest medical education in North America. The clinical opportunities at that time were not of the very first order, but the preliminary training in science was singularly full and thorough. The combination of Ramsay Wright's stimulating and thought-compelling lectures in general biology, with A. B. MacCallum's practical course in physiology, developed a set of men who to-day are leaders in American medicine: Llewellys Barker of Baltimore, Thomas McCrae of Philadelphia (John's elder brother, who also for a time was Lieut.-Colonel C.A.M.C. and head of the medical service of a Canadian general hospital), W. G. MacCallum of Columbia and now again of Johns Hopkins, T. Fletcher of Johns Hopkins (also Lieut.-Colonel C.A.M.C.), Oskar Klotz of McGill and Pittsburgh, and John McCrae. No school of this generation in North America can claim quite so brilliant a band of physicians and pathologists as original alumni. John McCrae had been Fellow in Biology at Toronto at the conclusion of his course in arts before coming to me as Fellow in Pathology at McGill after graduation in medicine.

It was this long-continued and thorough training in medical science that made John McCrae the sound and capable diagnostician and the inspiring teacher. His military habit of mind made that teaching precise; men had to be given definite instruction. To quote from a letter of Captain A. Malloch, C.A.M.C., author of that curiously interesting by-product of the war, the story of Finch and Baines, those two old physicians and friends who lie side by side in the chapel at Christ's in Cambridge: "Where other clinics have failed I am able to look back at some of his clear-cut pictures of disease. Dogmatism certainly has its place."

It came as no surprise to those of us who know his sterling qualities when we heard the news a few days before the all too sudden end, that he, who for two and a half years had been head of the medical service at "No. —

Canadian General," had been appointed consultant physician to the Imperial troops overseas. He was the first Canadian to whom the like position had been offered. We knew that the honour had been as well won as it had been unsolicited, that it was an honour to Canada, and that he would do Canada credit.

He felt the war intensely, and it had changed him. Loyal and straightforward as ever, he was no longer the cheery, light-hearted companion full of good sayings. In old times he was as apt with a story as was Abraham Lincoln. His memory was extraordinary. There was a notable journey which the late Earl Grey, when Governor-General, took with a chosen few, in canoes manned by Indians, from Lake Winnipeg down the Nelson River to York Factory, and thence by the Government steam yacht across Hudson Bay and around Labrador to Prince Edward's Island and the St. Lawrence. McCrae was of the elect. Lord Grey used to recount that during the expedition he estimated that each working day Dr. McCrae poured out anecdotes and *bons mots* at the average rate of eight an hour, or, in all, something over three thousand, and, notwithstanding, he never once heard him repeat himself! Now, the war was with him night and day, and, while kindly and devoted to those under him, he expected from them the same military spirit and sense of high responsibility, and was impatient when he thought either wanting. Not all at first understood the change or could rise to his level of service.

It is not, however, as soldier, pathologist, or physician, for his work upon agglutinins, mycotic aneurysms, and the oesophagus, or for his clinical studies upon the exanthemata, nor again as the most delightful and truest of friends that John McCrae will most surely go down to posterity. He was a master of English undefiled, and as a master of English and a poet his memory will be preserved. It is a commonplace that this war has brought with it an outpouring of verse such as England has not seen since the Elizabethan days. I have no hesitation in stating my belief that amongst the three or four imperishable poems owed to the war, poems which must become the heritage of the race—along, let us say, with Rupert Brooke's best sonnet and Julian Grenfell's noble lines—Jack McCrae's exquisite rondeau, "In Flanders Fields" must have place. Equally beautiful, though less generally known, is his "Brecon Town," which appeared some few years ago in the *University Magazine*, that magazine which, under the editorship of another Montreal physician and soldier, Sir Andrew Macphail, has brought to light so much that is best in Canadian thought, whether in prose or poetry. He had a singularly fine taste, and only gave forth that which was of the best. Thus, to my knowledge, but a dozen or so of his poems have been printed, one and all of high merit. Reading these two, his highest achievements, it is as though, with Brooke and Grenfell, he foresaw the inevitable end.

Colonel J. M. ELDER writes:

The funeral, which was held from No. — General Hospital (to which he had been removed to be under his friend Sir Bertrand Dawson) . . . was by far the largest and most impressive I have seen here; indeed, it was the most impressive military funeral I have ever seen anywhere. . . . All the officials here, especially Brigadier-General Wilberforce, were very kind to me, had sympathy for us in our trouble, and regret at the loss of our friend was universal. General Currie, General Morrison of course, General Dodds, and many others from the head quarters staff, came down specially for the funeral and marched in the procession, which was headed by Sir Bertrand Dawson and myself as chief mourners. Sir Arthur Sloggett was present to meet us at the grave, with his staff. I do not think there was a commanding officer in this area who was not there. The Base Commandant and D.D.M.S. were present, as was a large deputation from the Harvard Hospital and our dear old friend Sir Ahuroth Wright. Seventy-five of our personnel, headed by six staff sergeants and sergeants who carried the body from the gate of the cemetery to the grave, acted as an escort. . . . The firing party preceded the coffin. "Bonfire" (the Colonel's horse, to whom he was greatly attached), decked with the regulation white ribbon, followed the coffin, then the chief mourners and our rank and file, followed by our officers, who were nearly all present, and the rank and file party from No. — General Hospital, then

the officers from the base, followed by General Wilberforce and the D.D.M.S. About seventy-five of our Sisters, in their caps and white veils, lined up at No.—General, then they took their ambulances, met us at the grave-side, and again lined up. They were there at the special request of the commandant, and added much to the impressiveness of the ceremony. Colonel Adams made at the open grave the finest prayer to which I have ever listened. We watched the grave being rapidly filled in, and it was perfectly covered with the floral contributions which came from everywhere.

The day of the funeral was a beautiful spring-like day; none of us wore overcoats. You know the haze that comes over those hills at W—. I felt so thankful that the poet of "Flanders Fields" was lying out there in the bright sunshine in the open space he loved so well, instead of being cramped in that miserable city graveyard which he hated so much. I know this is only sentiment, but sentiment counts after all in this world-war.

JAMES SPOTTISWOODE CAMERON, M.D. Edin.,

FORMERLY M.O.H., LEEDS.

We regret to record the death, at the age of 73, of Dr. J. Spottiswoode Cameron, late M.O.H. for Leeds, which occurred on January 30th after a long illness. He received his medical education at the University of Edinburgh and graduated M.B. in 1868 and M.D. in 1870. His first appointment seems to have been that of resident dispensary medical officer at the Bradford Infirmary. In 1877 he became M.O.H. for Huddersfield; it was one of the first towns to adopt the compulsory notification of infectious diseases, and the system was introduced during Dr. Cameron's term of office; he was also physician to the Huddersfield Infirmary. In 1889 he was appointed M.O.H. for Leeds, a position which he retained until his health failed three years ago. He thus held this important appointment for twenty-six years and during that time did much to transform Leeds from one of the most backward towns, in a sanitary sense, to one of the most advanced; the main problem was created by the existence of a large area of slum property. He was a steadfast opponent of the evil principle of building industrial houses back to back, but local opinion was too strong and he had to give way on this point in many parts of the area. Nevertheless, he was able to accomplish a great deal, and the progress which has been made may be dated from 1895, when an area of 56 acres comprising 555 properties was scheduled under an improvement scheme undertaken by the municipality. During his administration the water carriage system of sewage was made general and infectious disease hospitals were erected. The efficiency of his work may perhaps be judged by the single fact that the death-rate of Leeds fell from an average of 22 per 1,000 to 15 per 1,000.

Dr. Spottiswoode Cameron was a member of the British Medical Association, and at one time took an active share in its work. He served on the old Parliamentary Bills Committee and also on the central Council; he was, in addition, vice-president of the Section of Public Medicine at the annual meeting in London in 1895. His published writings include books on the working of the Infectious Diseases (Notification) Act, on cholera and on nuisances and insanitary conditions, as well as a popular work on healthy houses; but his most important writings are contained in his annual health reports for Leeds. He was for many years a frequent contributor to our columns, and his wide knowledge of public health law and administration and his breadth of view and public spirit were much appreciated.

Dr. Cameron leaves a widow, a daughter, and two sons, one of whom is serving in the army, and the other in the Sudan Government service.

We regret to record the death on January 25th, at the age of 54, of Dr. THOMAS FRANK RICKETTS, medical superintendent of the Park Hospital, Hither Green, and the leading authority on small-pox. He was educated at Cheltenham College and Guy's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P. in 1889, the D.P.H. in 1892, and M.R.C.P. Lond. in 1899; the B.Sc. degree of the University of London in 1886, the M.B. and B.S. in 1890, and the M.D. (qualifying for gold medal) in 1891. Entering the service of the Metropolitan Asylums Board he was

appointed in 1892 medical superintendent of the hospital ships for small-pox, on the Thames, near Dartford; and later of the small-pox hospital at Joyce Green near the same place, and of the River Ambulance Service. In 1915 he became medical superintendent of the Park Hospital. As this long period (twenty-three years) in charge of small-pox hospitals included the epidemic of 1893 with about 2,500 cases, and that of 1901-1902 with about 10,000 cases, and also much diagnosis work at the receiving stations in London, it is obvious that the experience of Dr. Ricketts on this subject was enormous. What made his diagnosis unchallengeable was that he brought to his work a scientific mind of the finest calibre which made difficult work look easy. The extreme difficulty of making a correct diagnosis of every one of many thousands of cases presented as small-pox, in all varieties of place and time, is a commonplace. Dr. Ricketts's skill was almost uncanny. His work in this field was brilliant, and conducted with gentle decision and modesty. His scientific fame rests on the fact that he brought the varied points which bear on the diagnosis of small-pox into their true proportion and within the comprehension and power of the ordinary man. In his classical monograph, *The Diagnosis of Small-pox*, to which Lieut.-Colonel J. B. Byles, R.A.M.C., contributed the photographs, Ricketts displays much acute observation and reasoning, and shows that the key to the diagnosis is the distribution of the rash, this phenomenon being nearly always reliable for yielding a correct interpretation. Dr. Ricketts's great services to the public of London and indeed to the whole country, have never been generally known. He predicted with accuracy the heavy London epidemic of 1901-1902, and to him more than to any other single individual is due the prevention of a real disaster for London, and the saving of many thousands of lives. He it was who indicated the correct measures to be taken and the men to be employed to cope with a very ugly outbreak. He was admired as a master-mind, respected for his courage and common sense, attractive by reason of his sense of humour and correct opinions, and loved as a friend.

DR. DOROTHY EILEEN PRATT, assistant county medical officer for Hampshire, who died suddenly on January 10th, was the eldest daughter of Mr. Henry Pratt, V.D., of Exeter. She received her medical education at the School of Medicine for Women, Edinburgh, and graduated M.B., C.M. Edin. in 1898, taking the M.D. and M.Ch. degrees in 1912. She had served as superintendent of the State Hospital for Women and Children, Srinagar, assistant medical officer to the Plaistow Fever Hospital, medical inspector of schools under the Kent County Council, and assistant tuberculosis officer for Lambeth. She took a great interest in surgery and was the author of a report on two unusual cases of abdominal tumours published in the *Indian Medical Gazette* of 1912. She was a member of the British Medical Association.

Universities and Colleges.

UNIVERSITY OF ST. ANDREWS.

THE following degrees were conferred on January 19th:

M.B., Ch.B.—Kathleen I. David, W. A. Fraser, Dora M. Walker.

UNIVERSITY OF LIVERPOOL.

THE Diploma in Public Health has been awarded to G. W. Procter.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At an ordinary meeting on January 31st, when the President, Sir Frederick Taylor, was in the chair, Drs. Stanley Arthur Bull (New Zealand), Oliver Horsley Gotch (London), W. Hillgrove Leslie McCarthy (London), and W. Marshall Macdonald (New Zealand) were admitted Members. Licences to practise were granted to eighty-one candidates and diplomas in public health to two.

Drs. W. H. Hamer, A. F. Voelcker, F. F. Caiger, and Raymond Crawford were elected councillors.

The President was asked to nominate a committee to report upon the question of a Ministry of Public Health, and a memorandum upon the subject from the Royal College of Physicians of Edinburgh was received.

The President announced that the Harveian Oration will be delivered by Dr. Percy Kidd, the Bradshaw Lecture by Dr. Aldren Turner, and the Milroy Lectures by Dr. H. Kenwood during the present year, and that Dr. J. C. McVail had been appointed Milroy Lecturer for 1919.

Medical News.

THE Midwives (Ireland) Bill passed through its final stages last week.

DR. J. R. MASON has been elected an alderman of Newcastle-upon-Tyne. He has represented All Saints' Ward on the council for nearly twenty years.

THE London County Council has determined that the London lunatic asylums shall in future be designated mental hospitals, except in legal documents, where an alteration in the name would require an Act of Parliament.

THE London Insurance Committee has adopted a resolution welcoming the efforts of the Minister of Reconstruction to formulate a scheme for the immediate establishment of a Ministry of Health which would possess full maternity and infant welfare powers.

DR. MOND undertook to pay £62,000 as an endowment fund for the David Faraday Research Laboratory of the Royal Institution before 1926. His trustees have now anticipated the obligation, and have transferred £66,500 in 5 per cent. War Stock to the trustees of the laboratory.

A COURSE of four lectures on the electrical examination of the nervous system by Professor A. D. Waller, F.R.S., and Miss Mary D. Waller, B.Sc., lecturer on physics at the London School of Medicine for Women, began on February 6th at 5 p.m. in the Physiological Laboratory of the University of London, and will be continued on February 13th, 20th, and 27th, at the same hour.

THE Minister of Pensions has appointed an Advisory Council, consisting of thirteen surgeons, two engineers, and two limb makers, to advise on matters which may be referred to it with regard to the manufacture and supply of artificial limbs and appliances. Sir Charles Kenderdine, the new Director of artificial limbs supply to the Ministry, is the chairman of the Advisory Council, which held its first meeting on February 7th.

ACCORDING to a report of the results of the campaign against ankylostomiasis carried on in Costa Rica in 1916 by Dr. L. Schapiro under the auspices of the Rockefeller Foundation, the number of persons examined down to the end of the year was 83,921; of these 49,884 were found to be infected, of whom, 42,000 were cured.

THE twelfth award of the triennial Reuben Harvey memorial prize will be made on July 1st. The competition is open to all students of the various schools of medicine in Dublin and to graduates or licentiates of medical licensing bodies in Ireland of not more than three years' standing. Full particulars will be found in our advertisement columns.

GENERAL LEONARD WOOD, of the United States army, is not the only man who, beginning as a doctor, has become the head of an army. General Boriani, who commanded the Italian troops on the Asiago plateau, where in the face of heavy odds they successfully checked the advance of the enemy, was educated for the medical profession and for many years practised gynaecology.

NOTWITHSTANDING frequent bombardments the life of the University of Nancy has not been suspended. At the opening of the present academic year the French Minister of Public Instruction delivered an eloquent address in praise of the courage and public spirit of the teaching staff and the students. He then decorated the University with the Military Cross.

THE French Food Controller informed the Chamber of Deputies on January 28th that the uniform ration of 300 grams of bread by ticket which came into force in Paris and its suburbs on the following day was only a temporary expedient enforced at once to prevent food hoarding. It was intended by subsequent orders to supplement the allowance to persons who really needed a larger quantity.

AT the annual meeting of the Scottish Western Asylums' Research Institute in Glasgow, on January 29th, Dr. Oswald, physician-superintendent of the Glasgow Royal Infirmary, announced that with the help of an anonymous donor arrangements had been made for the endowment of a research scholarship in mental affections, of the annual value of £250, to be held at the Western Asylums' Research Institute. No appointment will be made during the continuation of the war.

M. GODART, Parliamentary Under Secretary for War in charge of the medical department of the French army, resigned unexpectedly last week because the Chamber refused to postpone the consideration of an interpellation with regard to an impostor who had succeeded in obtaining a medical commission. This person had contrived to get a certificate of competence as a surgeon from the Faculty of Lyons, for which city M. Godart is deputy. During a

brief but heated discussion certain deputies alleged that the war ministry was being imposed upon in a similar manner in other instances.

A MEETING of the West London Medico-Chirurgical Society was held at the West London Hospital on February 1st, Dr. A. J. Rice-Oxley being in the chair. Dr. Knyvett Gordon read a paper on the cancer problem and its clinical significance, illustrated by microscopic slides and coloured plates. Following the reading of the paper there was an interesting discussion, in which Dr. F. J. McCann, Major Jocelyn Swan, Mr. Aslett Baldwin, and others took part. Earlier in the evening Mr. P. Mackay from New Zealand exhibited an artificial hand and arm, which he had made for himself and since patented.

THE disease which causes what is called "contagious abortion" in cows is due to a bacillus which may infect cows which are not pregnant and also bulls, although the latter are not frequent disseminators. According to statements made by Dr. John McCall, Assistant Veterinary Officer of the Board of Agriculture, in a recent address to the Scottish Chamber of Agriculture, the disease is generally spread in the field by a cow which has aborted and has been allowed too soon to run with the others; it is spread also by the exposure at public auction of an animal known to have aborted. The disease is not serious in non-pregnant animals, and vaccination of the non-pregnant animal with living cultures of the bacillus renders it immune. Among between 2,000 and 3,000 animals so vaccinated in a single county during the last year or two less than 1 per cent. had aborted.

PLAGUE has never been endemic in Malta, but from time to time it has been imported, often with serious consequences. Dr. Bernard, M.O.H. of the island, has written a short report on the epidemiological investigation of certain cases of plague that occurred there in 1917. The disease broke out in March, but was localized quickly and rapidly suppressed. All the cases except one were males, their ages varying between 18 and 54 years. Four men died, and in three of them the nature of the disease was not recognized during life; one died at the Contagious Diseases Hospital at Gozo. The mortality rate was 50 per cent., well below the average. Most of the cases were bubonic in type. The ordinary sanitary precautions were adopted, and the disease was limited and prevented from spreading. Dr. Bernard is to be congratulated on the success he obtained in dealing with the outbreak.

IN a recent number of a Neapolitan medical journal (*La Medicina Pratica*, Naples, 1917, ii, 329) Professor A. Romano draws attention to a forgotten method of arresting epileptic convulsions described by the late Professor Baccelli as long ago as 1862. This consists in pressing the left thumb and index as an arch against the patient's temporal regions, while the right thumb makes counter-pressure in the hollow between the two complexus muscles over the cruciform tuberosity of the occipital bone. The method was improved by Solivetti, who directed that the left hand should make pressure in the frontal rather than the temporal region of the head, while the thumb and index of the right hand make counter-pressure beneath the occipital bosses. According to Professor Romano, this improved method of treatment will arrest the convulsions in 40 per cent. of cases of true idiopathic epilepsy; it is of no value in the case of other forms of epileptiform convulsions. The rationale of the method is obscure; Professor Romano thinks that it may act by cutting short the congestion of the base of the brain and of the medulla that has been supposed to be the immediate cause of the convulsions in true epilepsy.

LAST summer the Berlin Society for Race Hygiene presented a memorandum to the Reichstag in favour of making medical examination before marriage compulsory. The society urged that even before the war the process of the survival of the fittest had been seriously interfered with and that the war had destroyed a considerable portion of the most able-bodied males. Medical examination would lead to the early diagnosis, and possibly the cure, of conditions leading to sterility. The medical examiner would be bound by the rule of professional secrecy and would be authorized to communicate the result of his examination to the other party only when silence would mean concealment of evils. The society suggested that the certificates of fitness for marriage should be issued only by medical officers belonging to the applicant's place of residence. The certificate should deal only with the presence of diseases, or tendency to disease, notably mental and nervous disease and infectious disorders likely to be transmitted by marriage. The certificate should state whether the medical examination indicated the inadvisability of marriage.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

A PAMPHLET, entitled *A Searchlight on Germany*, has been written by Dr. William T. Hornaday for the American Defence Society, and is published in this country by Messrs. Bale, Sons, and Danielsson (London, price 3d.). It consists of three parts, dealing respectively with the blunders, crimes, and punishment of Germany. It is the sort of pamphlet which the people who want peace at the German price should be given to read.

MR. LEIGHTON KESTIVEN writes to correct an error in his article on ionic medication published in the JOURNAL of September 29th, 1917 (p. 423). In the last line of the first column the strength of the zinc iodide solution to be used in cases of middle-ear catarrh is given as 30 per cent. The correct strength is 3 per cent.

INCREASED EXPENSES OF PRACTICE.

COLLIERY SURGEON writes: Some weeks back it was stated in the BRITISH MEDICAL JOURNAL that expenses of doctors had increased from 10 to 35 per cent. My expenses, as allowed by the income tax officials, were in 1913 £280, in 1914 £276, in 1915 £400, and in 1916 £461. In 1917 my expenses (calculated) were £498.

THE FUTURE OF THE POOR LAW.

DR. A. WITHERS GREEN (Honorary Secretary, Poor Law Medical Officers' Association, Wardrobe Place, London, E.C.4) writes: All Poor Law medical officers should order through their booksellers from H.M. Stationery Office the "Report of transfer of functions of Poor Law authorities in England and Wales, 1918," Ministry of Reconstruction, Local Government Committee. Price 3d. net. It should be carefully studied as a first instalment of coming changes. This document coming first in a series of proposable changes would seem to save Poor Law medical officers from the clutches of the Insurance Act. At all events very definite promises are made which should conserve our interests provided we beforehand are prepared for action. It is surely the duty of each medical man to set aside some definite time weekly for reading and meditating on State intraprofessional subjects. To neglect this may be to fall into self ruin and collective disintegration, for we always are apt to be behindhand. I would suggest that each county should collect its Poor Law members and put their opinions together into one document, so that each individual and all unitedly would have a consensus of views before them. I would be pleased to receive such a statement. Montgomery and West Derby, for example, have thus acted and appointed a local secretary.

FINGER CRACKS.

DR. LEONARD J. KIDD (London) writes: I find that the most troublesome cracks occur within one-eighth of an inch from the border of the nails. They appear invariably soon after cutting the nails moderately short, provided the weather be damp and the temperature below 50° F. Dry, cold, frosty weather heals them rapidly, without local applications. Gloves worn all night after free rubbing in of vaseline, cold cream, or the "mel rose tablet," always relieve them. If I keep my nails long, I seldom have cracks. They are said to be specially frequent in that very common condition, mild hypothyroidism.

BOLISME.

BULIMY, or boulimy, or bulimia, or boulimia, still maintain a precarious existence in medical terminology. The derivation is from the Greek word *βουλιμία*, signifying an ox-like hunger. During the Middle Ages, however, the form *bolisme* came into use, apparently owing to an accidental error. We learn from Coulton's *Social Life in Britain from the Conquest to the Reformation* that John of Trevisa (1326-1412), in his translation of the book of Bartholomew de Glanville on the nature of things (Lib. xviii, cc. 25-8), after much in praise of the dog's character, wrote: "Houndes have other proprietes that ben not ful good, for houndes have contynnalle Bolisme, that is, immoderate appetyte." The recent introduction of the term "Boloism" is a curious example of two words of almost identical sound and spelling being derived from totally different sources.

LISTER AND THE BEGINNINGS OF THE ANTISEPTIC SYSTEM.

MR. H. NELSON HARDY (Thornton Heath, Croydon) writes: In Colonel Mayo-Robson's most interesting article on surgical dressings, etc., there is a sentence which seems to me of more than doubtful accuracy as to dates—"My first experience," he writes, "of an antiseptic operation, long before Lister introduced his system, was in 1875," the words italicized being those to which I desire to draw attention.

Now some eight years before the date mentioned, that is, in the year 1867, the year in which I became M.R.C.S., I was for six months a resident in the Liverpool Royal Infirmary, where Mr. E. R. Bickersteth, one of Liverpool's leading surgeons at the time, was a firm believer in Listerism, and had it carried out in his wards.

The system was then, I remember, in its transitory stage of carbolic oil, 1 to 5, which proved, of course, far too strong, and gave rise to much adverse criticism among us residents; but my point is that it had not only been introduced by Lister, but adopted by Bickersteth, eight years before the date mentioned by Colonel Mayo-Robson.

* * Mr. Nelson Hardy is no doubt right as to dates. The first paper in which Lister described the antiseptic method in its then early stage was published in the *Lancet* in parts at various dates during 1867. The first case there recorded was one of compound fracture of the left leg admitted into Glasgow Royal Infirmary on August 12th, 1865. His first general discussion of the system was contained in a paper read before the British Medical Association in Dublin on August 9th, 1867, published shortly afterwards in the BRITISH MEDICAL JOURNAL (1867, vol. ii, p. 246). The whole story is told in Sir Rickman Godlee's recent *Life*, where is quoted a letter from Bickersteth dated April 20th, 1869, in which he speaks of himself as "a firm disciple in the antiseptic theories and practice."

We may take this opportunity of referring to a point as to which another correspondent appears to be under some misapprehension. In the *Life* (p. 21) it is said that Lister while at University College became one of the champions trusted to maintain the reputation of that college, and that he fully justified the confidence of his fellow students; a quotation is made from a letter by Sampson Gamgee of August 30th, 1850, in which he thanked Lister "for having sustained the honour of the school after such a critical session as that of 1849-50. Had it not been for you University College would have been a nonentity at the examination for honours at the University." A reference to the *Calendar* of the university at that time shows that at the honours examination in 1850 Lister was second in anatomy and physiology (gold medal) bracketed third in chemistry, the late Dr. Pavy being second, and was first (gold medal) in structural and physiological botany. In 1852 he was first in surgery, taking the University scholarship and gold medal, and took honours also in physiology and comparative anatomy. Only one other student from University College appears to have taken honours at the M.B. examination of the University of London in that year.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posto restante* letters addressed either in initials or numbers.

PYROGENIC THERAPY.

WITH REMARKS ON COLLOIDAL METALS.

By A. G. AULD, M.D., M.R.C.P.,

SENIOR HONORARY PHYSICIAN, ST. MARTYLBONE GENERAL DISPENSARY;
SENIOR ASSISTANT PHYSICIAN, PRINCE OF WALES GENERAL
HOSPITAL; LECTURER ON MEDICAL DIAGNOSIS IN THE
NORTH EAST LONDON POST-GRADUATE COLLEGE.

The term "pyrogen" was first used by Burdon-Sanderson in 1875 to signify a fever-producing substance which he had prepared. Such substances, both protein and non-protein, have since then received ample recognition, though not from the therapeutic side. The subject, however, is one of high practical importance, and in many cases brilliant results may be obtained.

Early in 1915 I began the clinical investigation of various colloidal metals parenterally introduced. They were received from different sources and included those produced by both chemical and electrical methods. The first attempts were limited to subcutaneous injections, gold, platinum, silver, and copper being chiefly used. The results were meagre and uncertain. Sometimes slight elevations of temperature followed the injections. The next attempts were instigated by a consideration of the catalytic action of certain metals in relation to the oxidative processes in the peroxide-peroxidase system. It seemed conceivable that under local conditions of defective oxidation the introduction, if possible, of a new peroxidase might be beneficial, especially if there was some bar to the effective action of the natural peroxidase, which may be regarded as the iron in the haemoglobin and in the tissues. To this end I employed colloidal manganous hydroxide intravenously. The results were distinctly encouraging, and the matter is still under investigation. I also made a third series of trials in view of the well-known catalytic action of platinum, with the design of causing adsorption of toxin-antitoxin on the platinum particle introduced into the blood. If the antigen was not a soluble toxin, it might vice versa be neutralized by adsorbing the platinum. Numerous trials were made in diverse conditions, gold, silver, and copper colloids being also employed, the dosage (intravenous) varying from 2 to 10 c.cm. Favourable results were obtained, more particularly where the injection was succeeded by a rise of temperature, which, however, rarely exceeded 2° F. Cases of pneumococcal and streptococcal infections were influenced in this way, but as to the *modus operandi* it is difficult to conclude, as, except in the case of gases, the interaction of bodies adsorbed on the same surface is not characterized by evolution of heat, at least not to any very appreciable extent. There is, however, another consideration in that the metallic particles might adsorb both active (quadrivalent) oxygen and toxin, leading to combustion of the latter. The infective organism itself might also be destroyed by the active oxygen provided it adsorbed the particle so charged. It is to be remembered also that in a reducing system, as in the case of the liver, the metal would act as a reducing agent.

In the course of these investigations a bottle of colloidal platinum was opened which had been obtained from the manufacturers a year previously (May, 1915). It was perfectly transparent, of a very dark olive colour, and slightly acid to litmus. It was odourless and free from any trace of deposit. When given intravenously in the usual doses (3 to 7 c.cm.) it produced a new and severe reaction. In half an hour there was rigor, lasting for twenty minutes or longer, followed by rise of temperature to 104° or 105° F., with, in the next few hours, perspiration, sickness with vomiting (occasionally) and headache. The temperature then fell usually to subnormal. This reaction occurred alike in normal subjects and in those suffering from diseases characterized by moderate pyrexia, namely, subacute pleuritic and pneumonic conditions, and protracted paratyphoid fever. In these the fall of temperature coincided with a great improvement in the general condition. The entire syndrome exactly resembled the ague fit.

The following cases and charts are given in illustration:

CASE I.—Young woman, aged 20, admitted under me, April 14th, 1916, at the Prince of Wales Hospital, suffering from acute pneumonia and signs of plenry in the right side. Temperature 103°, pulse 140, respira-

tions 60. The pneumonia cleared up, but after a week, pus containing streptococci was aspirated from the side. A portion of rib was resected on April 24th and a tube inserted. The temperature then fell to 99°-100°; after five days it rose again to 103°. On May 2nd, when the temperature had temporarily fallen to 99.8°, 4 c.cm. of the colloidal

CHART 1.

platinum was given intravenously (marked by ×). This was followed by shivering and rise of temperature to 103.6°, perspiration, headache, and sickness. After six to eight hours, fall of temperature which reached 97.8° next morning, with great amelioration of the symptoms. After four days a second injection of 5 c.cm. was given, followed by rise of temperature to 104.4°, fall to 97.4° with rapid recovery.

CHART 2.

CASE II.—Man, aged 31. Admitted October 7th, 1916, with subacute pleurisy, right side, and pulmonary congestion over lower half of left lung. Temperature on admission 102°, pulse 116, respirations 32. Sputum contained pneumococci, also the fluid withdrawn from the pleural cavity. Temperature remittent. Rapid recovery after the injection (Chart 2, ×).

CASE III.—Man, aged 40, seen September 30th, 1916, suffering from left-sided pleurisy with effusion, of a subacute type, with signs of consolidation. Sputum abundant, containing pneumococci. Effusion diminished, but patient continued ill, temperature 99° to 101° F. After

CHART 3.

about three weeks (on October 18th) he received an injection of 5 c.cm. The temperature rose to 104° F., but instead of falling to subnormal in the usual time, fell to 99.8°, with a secondary rise to 101° F. on the following day. On the third day it became subnormal, and a speedy recovery ensued.

During the cold stage the blood pressure rises from 10 to 20 mm., and thereafter during the hot stage it falls to about the same extent below its normal level. The temperature reaches its height in two to four hours. Leucocytosis sets in during the rise, and may continue for forty-eight hours. After the critical fall in temperature the pulse-rate and respirations may show a sharp drop in frequency, but sometimes the decline is gradual. Facial herpes may follow the treatment. These reactions were not obtained in the acute stage of pneumonia or pleurisy, nor was benefit derived. Instead of a rise, a fall in temperature of several degrees may take place (negative phase), with subsequent return to the original level, or nearly so.

At the same time as these results were obtained, Jobling and Petersen,¹ and some others in the United States were employing the method of intravenous injection of typhoid vaccine which had been introduced in 1914 by Kraus and Ichikama in the treatment of typhoid fever. To Kraus, however, belongs the credit of showing

that precisely similar effects were obtainable by the use of *B. coli* vaccine, and that therefore there was nothing specific about the treatment. Miller and Lusk² reported striking results in arthritis, and Engman and McGarry³ in certain skin diseases by means of the vaccine, the reaction being in every respect identical with that which I had obtained with the colloidal platinum. "Non-specific vaccine therapy" and "protein shock therapy" were applied to the procedure. I can certainly add my testimony to the remarkable effects of the treatment in cases of recent arthritis.

When the supply of active colloidal platinum I had been using was nearly exhausted I was unable to obtain any colloidal metallic preparation capable of producing the reaction. It was not until September, 1917, I obtained a specimen of colloidal silver, which, in doses of 3 to 5 c.c.m., acted with particular intensity, even more so than the platinum colloid. Being informed by the manufacturers that this silver was protected in a special manner, I requested them to send me the protective suspension exactly as used, which they willingly did. On trying it clinically, I was somewhat surprised to find that it reproduced very faithfully the effects of the colloidal silver itself, bulk for bulk. The protective used was given as veal peptone 0.4 per cent., with 1 per cent. glucose. It gave a violet biuret reaction. The veal "peptone," of course, was the active agent, as the effect of the glucose alone was nil. The result was surprising also in view of the fact that I had frequently given larger doses of peptone intravenously without reaction. Such a discovery naturally led me to suspect all the colloidal metals supplied, as they all contain some albuminous substance as protective. Most of those I had used, including the very active platinum, were protected by gelatin. The gelatin protective was also prepared for me and on injection it certainly produced symptoms such as headache and malaise, but without the rise of temperature found in the active platinum. Whether this latter preparation owed its properties to an unusual state of dispersion of the platinum particles, or to some accidental impurity such as hydrazin, or to some toxic body formed by hydrolysis of the gelatin after prolonged keeping, is difficult at present to decide. Examined under the ultra-microscope, the platinum was certainly in a very fine state of division, and showed active Brownian movements. Although doubt is thus thrown on the colloidal metals, it cannot be affirmed that they are clinically inactive, as they may certainly produce results which are not accompanied by high temperature reactions. It is, however, very desirable that they be issued in a purer and more standardized form.

If the pyrogen which produced the reactions was not colloidal platinum it matters little therapeutically, as all pyrogenic substances in appropriate doses produce the same effects, whether killed bacteria, proteoses, nucleic acid, or protected colloidal metals, to mention only a few.

How is the reaction brought about? This is a disputed point. The minute quantity of certain of the pyrogenic substances necessary, and the apparent possibility of producing in experimental animals similar symptoms by such inert (non-protein) substances as kaolin and agar, would seem to favour the view which has recently been elaborated from a large number of experiments by Novy and De Kruif,⁴ that the matrix of the pyrogen is in the plasma, that it is always one and the same substance, namely, anaphylatoxin, and the antigen merely serves to evolve it. This is the reverse of the split protein theory of Friedberger and Vaughan.

The favourable effects (which in a considerable percentage of the cases means the termination of the disease by crisis) have been variously ascribed to leucocytosis, to rapid mobilization of antibodies, to stimulation of the non-specific ferments of the serum (protease and lipase), and alteration in the ferment-antiferment titre. Teague and McWilliams⁵ in an experimental investigation have not been able to confirm these as causal agents. They suggest an active passage of bacteriolytic substances from the blood into the lymph spaces which traverse the local area or areas of infection. Doubtless various factors are at work, but without the pyrexia there is no benefit.

Under present conditions, typhoid vaccine is probably the best pyrogen to use. Nucleic acid (2 per cent.) is not always available in a reliable form, and the same applies to albumose. From fifty to two hundred and fifty million

of killed typhoid bacilli are injected intravenously, — ~~500~~ ing to the strength of the patient and the existing state of the temperature. In apyrexial cases, as in many of the arthritides, the dosage should be greater than in cases of pyrexia. The treatment is specially adapted to sluggish cases of localized infective diseases, with low or moderate pyrexia. Little benefit results unless the full reaction is induced, and rarely more than one injection is necessary. An overdose is indicated by dyspnoea, cyanosis and diarrhoea. The injection should not be given while the temperature is high. Heart disease, high blood pressure, and rigid arteries are contraindications. With care in the selection of cases, the treatment is not dangerous and it is not necessary to produce "shock," nor is the expression "shock" therapy in my view desirable. As an antidote to this, I have used the prefix "pyrogenic."

It is a pleasant duty to acknowledge my indebtedness to Professors Bayliss and Donnan of University College, who have kindly granted me opportunities of consulting them in respect of certain problems presented by colloids and electrolytes.

TREATMENT OF WOUNDS OF THE CHEST,

WITH SPECIAL REFERENCE TO INFECTED
HAEMOTHORAX.

BY

MAJOR WILLIAM HUTCHINSON, C.A.M.C.

At the beginning of the war we were interested merely in the question of diagnosis of a haemothorax and whether or not aspiration of the blood was worth while. Fortunately it did not take very long to settle this latter point, and aspiration very quickly became a routine procedure. Simple aspiration was very soon followed by replacing the aspirated blood with oxygen in order to do away with the disagreeable symptoms sometimes produced by the rapid removal of a large quantity of blood from the pleural cavity. Thus, as far as the treatment of a simple haemothorax was concerned, perfection was reached; but there were other and more serious problems to be solved, and it was in the solving of those the most striking advance was made during the past year.

The problems with which we were confronted were three in number: how to deal with an open pneumothorax; how to deal with an infected haemothorax; how to deal with a foreign body in the lung. During the three years of the war a great deal of work has been done on these problems, and I am glad to say they have been solved.

In the treatment of wounds of the chest four classes must be distinguished.

I. A Non-infected Haemothorax or Pneumo-haemothorax.

The treatment of a simple non-infected haemothorax or a pneumo-haemothorax consists in merely aspirating the blood from the pleural cavity. This should be carried out in all cases in which more than two fingerbreadths of dullness can be made out. In my series of 450 cases 368 were aspirated; in the remainder there was not sufficient fluid to warrant it. The aspiration is done by means of the ordinary aspirating apparatus, but there are one or two practical points which, if carried out, make the procedure easier both for the patient and the surgeon. A local anaesthetic should be injected into the skin, muscles, and pleura in order to make the aspiration as painless as possible. After the injection of the anaesthetic a tiny incision should be made through the skin so that the round cannula will not be gripped by it. In the next place it is important to use a fair-sized trocar, as small needles are very easily blocked; another advantage in using a trocar is that when the sharp obturator is removed the blunt cannula can be moved about the pleural cavity without damaging the lung. If during the aspiration the patient begins to suffer pain in the chest and shortness of breath, the trocar can be disconnected

in the bottle and a little air allowed to enter the pleural cavity, and it will then be found that more blood can be withdrawn before the pain and distress return. In commencing to aspirate a chest, especially in cases in which a quantity of air is present in the pleural cavity, the bottle should not be exhausted before the trocar is connected, but should be exhausted gradually during the whole aspiration, as the sudden evacuation of air when the tap is opened might cause alarming symptoms.

The treatment of non-infected haemothorax in which there is a large amount of blood clot requires special mention, as there is a difference of opinion as to the course to be pursued. Personally, I believe the chest should be opened, all the blood and clot removed, the pleural cavity closed and the air aspirated. I would also recommend that this be done as early as the patient's condition will permit, as then the lung will get a chance to expand before adhesions form. There are two reasons for this: first, the removal of blood and clot by aspiration is impossible, and therefore we must depend upon absorption to remove them, and as this is necessarily a slow process the lung remains compressed for a long time and adhesions between the compressed lung and the chest wall become very firm; secondly, these cases in my experience formed the great bulk of the infected ones, and I am sure had they been treated by operation in the first place they would have escaped infection.

II. Open Pneumothorax.

The treatment of an open pneumothorax has been greatly improved during the past year and the results obtained at the casualty clearing hospitals are very encouraging. In this condition it is important to clean the wound thoroughly, to wash out the pleural cavity with saline, and to close the chest completely. This should be done early, as the condition of shock will be relieved by the closure and the danger of infection also decreased. If the patient's condition will stand it and the foreign body is fairly accessible it should be removed. If there seems a likelihood of infection having taken place, then 3 oz. of 1 in 5,000 flavine solution should be left in the pleural cavity and the usual after-treatment of an infected haemothorax carried out.

III. Infected Haemothorax.

We now come to the treatment of the most serious complication of chest wounds with which we have to deal at the base in France—that is, a haemothorax which has become infected. While doing surgical work in France during 1915-16 I was impressed by the great improvement in the results obtained by the cleaning out and closing of knee-joints which had become infected over the results obtained by the old method of drainage. In reviewing the good results obtained by closing the peritoneum in cases of general peritonitis, I came to the conclusion that if the lining membrane of the knee-joint and the peritoneal lining of the abdominal cavity could look after a considerable amount of infection, the pleura ought to be able to do the same. I therefore decided to apply this principle to the treatment of an infected haemothorax, and in the beginning of 1917 I initiated the line of treatment which I shall describe below. Before describing operative technique, I wish to say one word against palliative measures in these cases. Simple aspiration in infected cases is of no avail, as in the first place it is impossible to remove all the blood from the chest by this means, and in the second place the clot, in which lies the focus of infection, cannot possibly be removed through a trocar. Again, it is impossible to sterilize the clot by any known antiseptic which can be used in the pleural cavity, and therefore the only possible means of treating these infected cases is by operation.

The method to be applied in these cases is as follows: As soon as a haemothorax is found to be infected—by that I mean clinically and bacteriologically (not merely bacteriologically)—the patient is taken to the operating room and nitrous oxide and oxygen administered. A portion of rib, long enough to allow the hand to be passed through the opening, should be removed and the blood allowed to flow out. The clot is then removed by the hand, all parts of the cavity explored, and light adhesions broken down. Then by means of large pieces of gauze on dressing forceps the remainder of blood and clot is removed. After this the cavity should be washed out with saline and again mopped out and a running suture inserted in such a way

as to include the pleura and intercostal muscles. This suture should be left quite loose, so that a small quantity of some antiseptic can be poured into the pleural cavity. This antiseptic should be spread all over the walls of the cavity by means of a small piece of gauze on long dressing forceps. As soon as this has been done the running suture is drawn tight, thus closing the pleural cavity completely. The muscles and skin are then closed and a dry dressing applied.

Forty-eight hours after the operation the chest should be aspirated, thus removing a quantity of serum and air. This is done for two reasons—first, the serum by that time has lost its bactericidal properties, and then only becomes a menace; and secondly, by removing a good deal of the air from the pleural cavity a negative pressure is obtained which helps to re-expand the lung. It will be found that three or four aspirations are necessary during the course of convalescence.

The antiseptics which I have used in these cases include eusol solution, 1 in 2; a suspension of bipp in liquid paraffin in the following proportions, bipp $\frac{1}{2}$ oz., liquid paraffin 6 oz.; flavine solution 1 in 5,000, and normal saline, the amount left in the chest being 3 oz. The results from 29 cases treated in this manner are as follows:

			Remained Closed.		Reopened.
Eusol	2	...	5
Bipp	11	...	4
Flavine	2	...	3
Saline	1	...	1
Total	16	...	13

When considering this method of treatment the question naturally arises as to what cases should be treated in this way. In answer to this, I may say that at present I am inclined to close every case, and if the patient shows signs of becoming worse after the first post-operative aspiration, then it will be time enough to drain.

There are, however, certain types of infection which lend themselves to this form of treatment better than others, as the following table will show:

			Remained Closed.		Reopened.
<i>B. aerogenes capsulatus</i>	11	...	3
<i>Streptococcus</i>	1	...	6
<i>Staphylococcus</i>	1	...	0
<i>Pneumococcus</i>	1	...	2
<i>Diplobacillus</i>	1	...	0
Mixed infection	1	...	2

There is one point in the technique of the treatment by drainage which I wish to point out, and that is that the constant washing of the pleural cavity in early cases is harmful. In place of this washing the occasional filling of the cavity with a eusol solution 1 in 3 and good drainage should be substituted. In this way the body is stimulated to pour out serum into the cavity, which washes the pyogenic membrane from within outwards instead of merely washing its outer surface. In order to do this the patient is placed on his good side, so that the opening of the chest wall will be the highest point: a 1 in 3 solution of eusol is then allowed to flow gently into the cavity until it is filled, and then the patient is turned over and the fluid allowed to run out. This is repeated every second or third day, depending on the condition of the patient.

IV. Foreign Body in the Lung or Pleural Cavity.

A great deal of controversy has taken place during the past three years as to the treatment of a foreign body retained in the lung. I have had the opportunity of treating a large number of cases and have talked to a number of surgeons and physicians, and as the result of my own experience and that of others I have come to the conclusion that the question must be decided separately in three types of hospitals: the casualty clearing hospital, the base hospital in France, and the base hospital in England; and that a surgeon in one area is not in a position to dictate to a surgeon in any other area. As all my work has been done in a base hospital in France, I am only in a position to discuss the treatment which should be carried out in cases with retained foreign bodies in the lung during the interval from the time they leave the casualty clearing hospital to the time they arrive in England.

As a result of experience with 450 cases, and from reports received from other surgeons similarly situated, I

am convinced that no attempt should be made to remove the foreign body from the lung while the patient is in a base hospital in France.

RESULTS.

In my series of 450 cases there were 27 deaths, the causes of which when examined will show the hopelessness of certain cases and will also point to one problem in surgery which has not been solved—that is, cases in which the infected haemothorax is pocketed. In these 27 cases the causes of death were as follows:

1. Septicaemia, due to pocketing	Drained.
2. Septicaemia " " " " " " " " " "	Drained.
3. Septicaemia " " " " " " " " " "	Drained.
4. Abscess of lung " " " " " " " " " "	Drained.
5. Pneumonia and empyema (opposite side), haemothorax " " " " " " " " " "	Drained.
5. Gangrene of lung " " " " " " " " " "	Drained.
7. Septicaemia " " " " " " " " " "	Drained.
8. Septicaemia " " " " " " " " " "	Drained.
9. Moribund, time of operation " " " " " " " " " "	Drained.
10. Septicaemia, due to pocketing " " " " " " " " " "	Closed and reopened.
11. Septicaemia, due to pocketing " " " " " " " " " "	Closed and reopened.
12. Septicaemia, due to pocketing " " " " " " " " " "	Closed and reopened.
13. Pyaemic abscesses (both lungs) " " " " " " " " " "	Closed and reopened.
14. Pneumonia and empyema (opposite side), haemothorax " " " " " " " " " "	Closed and reopened.
15. Acute gas gangrene of chest wall " " " " " " " " " "	Closed and reopened.
16. Septicaemia " " " " " " " " " "	Closed and reopened.
17. Septicaemia " " " " " " " " " "	Closed and reopened.
18. Gas gangrene of chest wall " " " " " " " " " "	Closed and reopened.
19. Double pneumonia " " " " " " " " " "	No operation.
20. Bronchopneumonia and tuberculosis " " " " " " " " " "	No operation.
21. Septicaemia " " " " " " " " " "	No operation.
22. Gas gangrene (one side), pneumonia and empyema (opposite side) " " " " " " " " " "	No operation.
23. Streptococcus (arm), mediastinitis, abscess of lung " " " " " " " " " "	No operation.
24. Pneumonia (opposite side) " " " " " " " " " "	No operation.
25. Double bronchopneumonia " " " " " " " " " "	No operation.
26. Secondary pulmonary haemorrhage, infected haemothorax " " " " " " " " " "	Drained.
27. Died on table, before operation.	

CONCLUSIONS.

1. All cases of wounds of the chest should be treated in special wards or special hospitals.
2. Careful charts should be kept which record temperature, pulse, and respirations four times a day.
3. Early diagnosis of infection is important.
4. Every case in which there is more than two finger-breadths of dullness should be aspirated.
5. Cases of open pneumothorax should be closed as early as possible.
6. Cases in which there is a large amount of clot in the chest should be opened, blood and clot evacuated, and the chest closed. This should be done as early as possible.
7. Cases in which the haemothorax is found to be infected should be opened, washed out, and closed, some antiseptic being left in, preferably an emulsion of bipp in liquid paraffin.
8. Post-operative aspirations must be done in all closed cases the first forty-eight hours after operation.
9. No attempt should be made at the base in France to remove a foreign body from the lung.

THE MODERN TREATMENT OF EMPYEMA BY ANTISEPTICS.

By R. ATKINSON STONEY, F.R.C.S.I.

VISITING SURGEON, ROYAL CITY OF DUBLIN HOSPITAL; MÉDECIN MAJOR 2ÈME CLASSE, ARMÉE FRANÇAISE.

For all practical purposes cases of empyema may be divided into two classes—(a) those easily cured by simple surgical methods, and (b) those difficult or impossible to cure even by such extensive surgical operations as Estlander's or Schede's thoracoplasty or pulmonary decortication.

This difference is chiefly due to the fact that in the latter cases the condition has become chronic, either through neglect or inefficient surgical treatment in the early stages, with the result that the lung and diaphragm have become covered by granulation tissue, which by its further development into fibrous tissue renders the walls of the pus-producing cavity rigid so that they cannot collapse and so obliterate the cavity. Down to quite recently it has generally been believed that an empyema could be cured only when the cavity of the pleura was obliterated either by distension of the lung to meet the chest wall, or collapse of the chest wall to meet the

lung; the first process occurring in those cases that were easily cured, and the latter being brought about by Estlander's or Schede's operation in the cases which resisted ordinary treatment.

That this idea was wrong is, I think, proved by the histories of the following three cases treated in France last year:

CASE I.

Arab, aged 17, found during the inspection of an outlying hospital, with an empyema of the right side which had burst through the chest wall in two places—in the fourth space in the nipple line and in the sixth space in the anterior axillary line. He had an evening temperature of 102° to 104°, and was in a very weak and emaciated condition. On May 19th a piece of the eighth rib was removed in the scapular line, and the pleura opened. One pint and a half of odourless pus was evacuated, and the pleural cavity was freely douched with Dakin's solution and hot water, and a large double drainage tube inserted. He was dressed daily and syringed with Dakin's solution and hot water. The discharge, which was at first very copious, rapidly diminished, and at the end of four weeks there was only a little serous discharge on the dressings, though there was still a large intrapleural cavity, shown by the fact that from 6 to 8 oz. of lotion could be injected without pressure or discomfort. The drainage tube was left out and the wound closed without rise of temperature; on two or three occasions during the following week a probe was inserted, but, as only a little clean serum escaped and there was no further rise of temperature, the wound was allowed to cicatrize, and the patient was discharged in the beginning of July. The physical signs showed that the lung was still contracted and that there was a considerable pneumothorax.

CASE II.

An Arab, aged 18. This case was very similar; he had an empyema of the left side which had burst through the chest wall and formed a large subcutaneous abscess over the sixth space in the nipple line. On June 1st a piece of the eighth rib was removed in the scapular line, and when the pleura was opened nearly four litres of thin, foul-smelling pus escaped. The pleural cavity was douched with Dakin's solution and hot water and a large double drainage tube inserted. The further history and treatment was the same as the previous case. In three weeks the discharge had lessened so much that the drainage tube was left out and the wound closed. Here again a probe was passed on a couple of occasions and only a little serum escaped. He was discharged healed, early in July.

CASE III.

A French soldier, aged 30, said that he had been partially buried by an explosion nine months previously. An operation was performed and a tube put into his left side, from which there was daily discharge up to the time he was seen by me, last June, when he had a sinus in the posterior axillary line, about the level of the eighth rib, through which a probe could be passed for six to eight inches. The discharge was copious, and there was a slight evening rise of temperature. The sinus was enlarged, a drainage tube inserted, and the cavity washed out daily with Dakin's solution and hot water. The discharge lessened rapidly and the temperature became normal; the tube was left out at the end of three weeks, and the discharge being only serous the wound was allowed to close and the patient was discharged from hospital at the end of five weeks, healed and apparently well, though he still had a considerable pneumothorax.

The first two cases were neglected acute empyemas which had been allowed to burst externally, in fact the "empyema of necessity" of the early writers; and the third case was probably a haemothorax, which had been drained and allowed to become septic. In all three cases the result of treatment came as a great surprise, as it had been thought that an extensive operation would have been necessary; the drainage and douching was only done as a preliminary measure to get the cases as clean as possible before undertaking an Estlander's operation.

Since treating the above cases and returning to Dublin, I have read of Tuffier's treatment of empyema by the Carrel-Dakin method. He claims the same results—that is, that the discharge gradually lessens and finally is only serous, and as soon as this occurs, or it is proved that the discharge is sterile or almost so, by bacteriological examination, he removes the tubes and allows the wound to close. He draws attention to the fact that the patient is cured and the thoracotomy wound closed, while there is still a free space in the pleural cavity, and this is the real crux of the whole subject; for up to this all our efforts have been directed to obliterating this space, as it was considered impossible to obtain a cure of a case of empyema until this space had ceased to exist. In future our efforts must be directed to sterilizing the walls of this space, which has been proved to be possible, perhaps not in every one of these cases, but certainly in a large number of them. Whether we attempt to do this, as outlined in the above cases, by frequent washing with some reliable antiseptic by

means of a syringe, or by more frequent washings, as in the Carrel-Dakin treatment, will depend on various factors, such as personal predisposition, nursing facilities and idiosyncrasies of the patient. It would seem natural to suppose that quicker and surer results could be obtained by the two-hourly flushings of Carrel-Dakin than the daily or twice daily flushings by syringe when dressing the case.

Conclusions.

1. Most if not all cases of empyema can be cured without resort to such mutilating and dangerous operations as thoracoplasty and pulmonary decortication, because it is not necessary to obliterate the pleural space, but merely to render its walls sterile, and this is possible by frequent washings with hypochlorite solutions.

2. Flushing of the pleural cavity with hypochlorite solution is not dangerous provided there is a free exit for the fluid, as by the use of a double drainage tube.

3. The earlier this treatment is instituted the sooner and more surely will a cure be obtained, as there will be less formation of granulation and scar tissue, and the organisms will not have had time to entrench themselves deeply in the tissues, and will therefore be more exposed to the action of the antiseptic.

4. The drainage should be free, and the opening should not be valvular; if a Carrel tube is used it should be introduced as far as possible into the pleural cavity through a large drainage tube, so that the fluid, starting at the most remote part of the septic space, passes down over its walls and escapes freely between the Carrel tube and the drainage tube.

5. The opening is most suitably made by removing one inch of the eighth rib in the scapular line, as this is the most dependent spot for practically all positions, and there is no fear of its closure by the rising diaphragm.

PARALYSIS FOLLOWING ARTERIAL INJURIES.

BY

CAPTAIN HAROLD BURROWS, R.A.M.C.(T.F.).

AMONG the accidents of war injury of a main blood vessel is common, yet little inquiry appears to have been made into the effects upon the structures which lie within the area of distribution of the wounded vessel. Injury of a main artery—for example, the common femoral, the popliteal, or the brachial—may produce immediate and remarkable consequences in the affected limb. As the ensuing symptoms are paralytic they have been apt to be regarded either as "functional" or as arising from concomitant nerve lesions, for, owing to the close association and common anatomical relations between the vessels and the nerves, simultaneous injuries of the structures are of frequent occurrence.

As the following cases will show, extensive paralytic phenomena may follow a vascular lesion independently of any direct traumatism of the main peripheral nerves. That these sequences are not infrequent is shown by our experience at the — General Hospital, and also by knowledge gained at the other military hospitals in the neighbourhood.

CASE I.

Signr. S. H., wounded on May 26th, 1917, was admitted on June 8th. A note taken on June 14th states that there was an entry wound in the right arm 3 in. below the tip of the acromion process and an exit at the middle of the inner surface of the arm. There was no injury to bone. The note from the casualty clearing station was: "Brachial artery tied, and temporary suture of median nerve."

FIG. 1.—Shaded area shows extent of loss of sensation to light touch, the upper limit of which is marked by 1; 2 defines the upper limit of loss of sensation to pin-pricks.

The patient complained of pain in the hand and fingers and a "tingling, horrible sensation" in the same area. He said his

"funny bone" was tender, and that pain shooting down to the fingers could be caused by pressure applied to the ulnar nerve at the elbow.

There was anaesthesia to light touch and pressure, as shown in Fig. 1, and it is notable that the loss of pressure sense was slightly greater than the loss to light touch. There was also complete loss of sense of position in the wrist and all joints below the wrist. There was absolute paralysis of all muscles below the elbow. The right hand was warmer than the left. The radial pulse could be felt, but the pressure within it was too low for accurate estimation with Riva-Rocci apparatus. A pressure of less than 20 mm. of mercury was sufficient to obliterate the pulse. The maximum systolic blood pressure in the left arm was 118.

There can be no question that the clinical symptoms in this case cannot be accounted for by peripheral nerve injury, for the musculo-spiral escaped damage, and yet the forearm muscles were completely paralysed.

CASE II.

Q.M. Sergt. W. G. D. Wounded on June 23rd, 1917, was admitted on June 25th, under the care of Captain E. T. Tatlow, R.A.M.C.(T.F.). The note from the casualty clearing station was: "Through wound of left arm and forearm, passing through bend of elbow and wounding brachial artery. Wound explored through separate incision at bend of elbow. Artery tied. Bipp dressing. Packing for serious oozing. Scalp wound cleaned."

There was a small entry wound on the inner posterior surface of the left arm, with a small exit wound on the radial side of the anterior surface of the forearm. Both wounds had been excised, bipped, and firmly plugged with gauze. There was an oblique operation wound in front at the bend of the elbow, and this also had been sutured. The limb was fixed on an internal rectangular splint. There was no injury to the bones or to the elbow-joint, the projectile having passed anteriorly to these structures. The left hand and forearm were much swollen and colder than the right hand and forearm, and there was considerable bruising in the neighbourhood of the elbow. No radial pulse could be felt. He complained of "pins and needles" in the left hand, from the wrist to the tips of the fingers. He felt this especially if he coughed, sighed, or took a deep breath.

There was "glove" anaesthesia of the left hand (Fig. 2), including the loss of appreciation of light touch, pin-pricks, pressure, tuning-fork vibrations, and sense of position; further, there was complete paralysis of all the muscles below the elbow, except the supinator longus and extensor carpi radialis longior, which were not paralysed. In this connexion it may be noted that the blood supply of these two muscles is derived from the superior profunda artery. The paralysed muscles felt hard and inelastic. On July 9th it was noted that there had been no material alteration in the loss of power or sensation since the patient's admission. The oedema had become less, but it had not disappeared, although the limb had been elevated; the hand was now warm.

FIG. 2.—Shaded area shows loss to light touch; 2 shows upper limit of loss to pin-pricks; and 3, the upper limit of loss to deep pressure. The area of loss to light touch alone has been defined on the palmar surface owing to discomfort caused to the patient during examination of this region. The arrows show the direction of the wound.

In this case it is clear that the ulnar and median nerves may have been injured, but it is equally clear that the musculo-spiral escaped. Consequently, some factor additional to peripheral nerve injury is required to explain the symptoms.

CASE III.

Pte. S. U. F., wounded August 23rd, 1917, was admitted on August 25th under the care of Captain J. H. C. Fegan. He presented three wounds: (1) Gunshot wound of left leg, with compound fracture of left tibia and fibula; (2) a large vertical wound in the left deltoid region, tightly plugged with gauze, over which the skin was sutured; (3) a long vertical wound on the inner side of the left arm, also plugged tightly with gauze and sutured. The notes accompanying the patient from the casualty clearing station did not mention any arterial injury.

The patient had pins and needles in the left hand for the first twenty-four hours, but this symptom disappeared. He complained of a "feeling of pressure" in the hand. The radial pulse could not be felt. There was moderate oedema of the forearm and hand, and the muscles felt hard, inelastic, and tender. The fingers and thumb were flexed at all the joints.

The wrist was neither flexed nor extended. All the muscles below the elbow were completely paralysed. Sensation for light touch, pin-pricks, and pressure was lost up to the level of the wrist (Fig. 3).

FIG. 3.—Shaded area represents loss of sensation to pin-pricks; 2 marks the upper limit of anaesthesia to pressure, and 3 the upper limit of anaesthesia to light touch. On the palmar surface the loss to pin-pricks alone was investigated, as the examination of this region caused the patient to suffer pain.

CASE IV.

Pte. E. G. was wounded on May 3rd, 1917. The note from the casualty clearing station was: "Femoral vessels tied." When admitted under the care of Captain J. H. C. Fegan there was a vertical operation wound on the antero-internal aspect of the right thigh, and a similar one at the same level over Hunter's canal. A large drainage tube connected these two wounds. The note taken on May 31st recorded an extensive area in the leg and foot, as shown in Fig. 4, where sensation to light touch

FIG. 4.—The shaded area represents loss of sensation to light touch.

was lost (other sensations were not tested). There was persistent foot-drop with rectangular talipes. The peronei were hard, bulky, and weak, but not completely paralysed. The extensor longus hallucis and all the other anterior leg muscles were weak, though not completely paralysed.

In this case, imperfect as the record is, it is still clear that there is a muscular weakness and a loss of cutaneous sensibility that cannot be accounted for by any direct injury of the peripheral nerves.

CASE V.

Pte. T. P., wounded on June 13th, 1917, was admitted on June 16th, under the care of Captain Graham-Jones, R.A.M.C. The note from the casualty clearing station was: "Gunshot wounds left thigh (three wounds). Haemorrhage. No posterior tibial pulse. All wounds excised. External branch from popliteal artery ligated. Also perforating branches of the femoral. BIPP and paraffin gauze. Progress: Foot cold and white for twenty-four hours, then signs of returning circulation; can now feel toes. Dressed. Slight discoloration over instep and tips of toes. Wound healthy."

On admission to a general hospital on June 16th, under the care of Captain Graham-Jones, the toes and a portion of the dorsum of the foot were cold and discoloured. Tight gauze packing in popliteal wound. No pulsation was felt in dorsalis pedis or posterior tibial. The whole left leg was swollen and hard; the foot was warm except in the discoloured area. There was no loss of sensation to pin-pricks except in area of gangrene, but there was absolute paralysis of all muscles below the knee except the soleus and gastrocnemius, and these were capable of the slightest movement only. Amputation above the knee was performed on June 27th.

Examination of the leg showed a striking change of colour of all the muscles of the leg, which were pale, and in their lower portions had hardly a tinge of red. The gastrocnemius was affected in its lower two-thirds and the soleus in its lower third. The upper portions of these muscles were of normal colour and looked healthy, and the transition from this healthy muscle to the pale altered tissue below was gradual, the muscle in the intermediate zone having a streaky appearance, bundles of red fibres being interspersed among bundles of discoloured fibres.

The pallor of the affected muscles was striking and at once arrested attention as an abnormal condition. Portions of these muscles were sent to Captain A. W. Stott, who prepared sections of them for microscopical examination. His report is given later.

CASE VI.

Pte. H. T. was wounded on June 16th, 1917. The note from the casualty clearing station was: "Penetrating wound of right thigh just below Poupart's ligament. Artery three-quarters severed; artery ligated. Bled freely from lower part. Pulse felt in left foot."

The note made on June 24th recorded that the patient had early gangrene of the toes and the neighbouring portion of the foot. There was absolute paralysis below the knee, and the muscles felt hard and stiff. Amputation was performed above the knee. The muscles of the leg were pale and bloodless. Unfortunately no observations were made on the cutaneous sensibility in this case.

CASE VII.

Shoering-smith J. S. was wounded on July 17th, 1917. The note from the casualty clearing station was: "Shell wound of thigh, left, July 18th, 1917. Wound excised; foreign body removed; superficial femoral and deep femoral veins divided—ligatured; bipped and sutured." He was admitted on July 19th under the care of Major Moffat. The note made on the following day recorded a transverse sutured wound $7\frac{1}{2}$ in. long on the front of the left thigh, 4 in. below the centre of Poupart's ligament. There were no gross signs of inflammation in the neighbourhood of the wound, and the patient seemed fit except for his pallor; he said that he had lost much blood when wounded. No pulsation could be felt in the posterior tibial or dorsalis pedis of the wounded limb, but blood was circulating in the foot and toes, and there was no gangrene or blistering.

The patient complained much of subjective sensation in his left foot and leg, which he described in these words: "My foot feels as if it were being drawn up tight in an onion net; the feeling works up into my ankle and shin, and keeps me from sleeping; it is a most unpleasant sensation; you would think my foot was coming off."

There was extensive impairment of sensibility of the leg and thigh, as shown in Fig. 5, but it was particularly noticeable

FIG. 5 (Case VII).—Shaded area represents loss of sensation to pin-pricks.

that the boundary of the anaesthetic area was not perfectly definite—that is to say, there was an intermediate zone, perhaps 1 in. wide, in which pin-pricks sometimes were and sometimes were not felt. There was a small area on the anterior surface of the thigh in its lower third where the anaesthesia was similarly incomplete. There was loss of sense of position in all joints distal to the tarsus. Deep pressure sense was lost up to a level about 2 in. above the ankle-joint. The boundary line of this loss was slightly irregular—that is to say, it was serrated, but might be described as belonging to the stocking type. There was complete paralysis of the extensor longus hallucis, and of all the flexors of the toes. There was very slight power in the long extensors of the outer four toes. The tibialis anticus and peronei were weak but not completely paralysed. The gastrocnemius, soleus, and tibialis posticus were nearly normal, though there was some obvious weakness in these also.

CASE VIII.
